HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

COMPUTATION OF THE MAGNETIC POTENTIAL INDUCED BY A COLLECTION OF SPHERICAL PARTICLES USING SERIES EXPANSIONS

STÉPHANE BALAC¹, LAURENT CHUPIN² AND SÉBASTIEN MARTIN³

ABSTRACT. In Magnetic Resonance Imaging there are several situations where, for simulation purposes, one wants to compute the magnetic field induced by a cluster of small metallic particles. Given the difficulty of the problem from a numerical point of view, the simplifying assumption that the field due to each particle interacts only with the main magnetic field but does not interact with the fields due to the other particles is usually made. In this paper we investigate from a mathematical point of view the relevancy of this assumption and provide error estimates for the scalar magnetic potential in terms of the key parameter that is the minimal distance between the particles. A special attention was paid to obtain explicit and relevant constants in the estimates. When the "non-interacting assumption" is deficient, we propose to compute a better approximation of the magnetic potential by taking into account pairwise magnetic field interactions between particles that enters in a general framework for computing the scalar magnetic potential as a series expansion.

1. INTRODUCTION

This work is devoted to the study of a way of computing the magnetic field induced by a cluster of metallic particles subjected to the static magnetic field of a Magnetic Resonance Imaging (MRI) device. These magnetic particles locally induce magnetic field inhomogeneities. In some context, magnetic field inhomogeneities are annoying since they perturb the imaging process giving rise to susceptibility artifacts in the image [22, 2]. In other contexts, the magnetic field inhomogeneities induced by the metallic particles can be exploited in the imaging process for specific medical diagnostic. For instance, magnetic particles are used for the magnetic labeling of cells and MRI detection. In stem cell therapy, MRI offers the potential of tracking labeled cells in vivo [20]. Tumor cell detection can be achieved by labeling the cells with iron oxide-based contrast agents [24]. We can also quote the measurement of susceptibility effects due to blood in brain micro-vessel networks and application to the MRI studies with or without contrast agents [4, 12]. As well, pathological iron deposit in the brain plays a role in neuro-degeneration [26] and iron has been identified as a potential MRI biomarker for early detection and diagnosis of Alzheimer's disease. Thus, mapping the brain iron content, identifying and quantifying iron deposits using MRI could provide new ways of diagnosing Alzheimer's disease at an early stage [8]. This list of examples is not exhaustive.

Over the years, numerical simulation has become an essential tool in the research field of MRI, for a better insight into the physical mechanisms that govern the MR signal, for improvement of simulation sequences and protocols, for safety assessment of medical devices *etc.* The above mentioned problem is however tricky from a numerical simulation point of view. Indeed, the large amount of particles prevent the use of standard numerical approaches such as the Finite Difference Method [16], the Finite Element Method [10] or methods based on integral formulations [23] since they require the meshing of the computational domain, taking into account metallic inclusions, which is prohibitive from a computational point of view. For such a problem, in the existing MRI literature, the calculation of the variations of the static magnetic field is usually done by adding the analytical solutions of the magnetic field due to sources described by simple geometrical shapes: point sources, spheres, (infinite) cylinders. The simplifying assumption is that the field due to each source interacts only with the main magnetic field but does not interact with the fields due to the other sources, see e.g. [27, 3, 14, 13, 19] and references therein. This assumption is referred as the "non-interacting assumption". Sometimes these analytical models are coupled with statistical methods [25] or Monte-Carlo methods [3].

The goal of the present work is to study from a mathematical point of view the validity of the "non-interacting assumption". At best, the assumption is justified experimentally in the above mentioned references. Intuition suggests that this assumption is fulfilled when the particles are "far enough" but that it is defective when the particles are "close" to each other. We will quantify in the document how "far" and "close" have to be interpreted.

The features of the particles involved in the above mentioned applications are generally not known precisely. Their shape and size can vary around a mean configuration. However, in order to simplify the mathematical investigations, we assume that all the particles have the same shape and size corresponding to the mean configuration. Namely, we denote by $\Omega_1, \dots, \Omega_N$ the open sets corresponding to the particles, see Fig. 1. For simplicity and clarity, we assume that the particles are spherical, *i.e.* the open set Ω_j , $j \in \{1, \dots, N\}$, is a ball centered at position $c_j \in \mathbb{R}^3$. We also assume that all the balls have the same radius denoted by $\varepsilon > 0$. The boundary of Ω_j is denoted by Σ_j . It corresponds to the sphere centered in c_j with radius ε . We also denote by Ω^c the surrounding area, *i.e.* $\Omega^c = \mathbb{R}^3 \setminus \bigcup_{j=1}^N \overline{\Omega_j}$, and by Σ the boundary of Ω^c , *i.e.* $\Sigma = \bigcup_{j=1}^N \Sigma_j$. In this study, besides ε , a key parameter is the minimal distance between two particles defined as

$$\delta = \min_{\substack{i, j \in \{1, \dots, N\} \\ i \neq j}} |c_i - c_j|. \quad (1)$$

FIGURE 1. Notations used to describe the cluster of metallic particles.

Moreover, we denote by $R > 0$ the radius of a ball containing all the particles. Assuming the particles are not in contact to each other and using volume considerations, we have the following constraints:

$$\delta > 2\varepsilon \quad \text{and} \quad N\delta^3 < 8R^3. \quad (2)$$

We also assume that the particles are made of the same paramagnetic or weak ferromagnetic material and we denote by $\mu_p > 1$ their relative magnetic permeability.

As mentioned earlier, the effect of the main static magnetic field \mathbf{H}_0 of the MRI device (assumed to be constant in direction and strength in the area where the particles are located) is to generate a secondary magnetic field induced by the metallic particles. As usual in magneto-statics, the mathematical problem can be formulated in term of the scalar magnetic potential φ . Our main result states that the error made when approximating the magnetic potential φ by the sum of the magnetic potential φ_{c_j} induced by the particles $\Omega_j, j = 1, \dots, N$ taken individually, *i.e.* under the "non-interacting assumption", satisfies, in a convenient norm to be specified later, the following estimate

$$\left\| \varphi - \sum_{j=1}^N \varphi_{c_j} \right\|_{\mathbb{W}^1(\mathbb{R}^3)} \leq 4\sqrt{\pi} \frac{(\mu_p - 1)^2}{\mu_p + 2} N \left(\frac{\varepsilon}{R} \right)^{\frac{3}{2}} \left(\frac{2\varepsilon}{\delta} \right)^3 \left(B_3 + 3 \ln \left(\frac{2R}{\delta} \right) \right) R |\mathbf{H}_0|,$$

where the constant B_3 was found to be $B_3 = 142 + 3 \ln 2 \approx 144.1$.

This result is consistent with intuition: when considering a very large number of particles able to fill the area of interest completely and evenly, the ratio $\left(\frac{2\varepsilon}{\delta}\right)^3$ is proportional to the volume fraction of particles. Thus, when the volume fraction is low, that is to say when the particles are spaced at a fairly large distance from each other, computing the magnetic potential by neglecting magnetic field reciprocal interactions between particles gives a quite accurate approximation.

The paper is organized as follows. In Section 2, we introduce and study the magneto-statics problem. In Section 3, we study the accuracy of the "non-interacting assumption" and prove the above mentioned error estimate together with a point-wise error estimate. In Section 4, we study the approach consisting in taking into account pairwise interactions in the computation of the magnetic potential and we prove an error estimate in that case. Finally, Section 5 is devoted to numerical illustrations.

2. THE MAGNETOSTATIC PROBLEM

2.1. Formulation for the scalar magnetic potential. The magnetostatic problem described in introduction, expressed for the magnetic field \mathbf{H} , reads

$$\begin{cases} \operatorname{rot} \mathbf{H} &= \mathbf{0} & \text{in } \mathbb{R}^3 \\ \operatorname{div} \mathbf{H} &= 0 & \text{in } \Omega_1, \dots, \Omega_N \text{ and } \Omega^c \\ [\mu \mathbf{H} \cdot \mathbf{n}] &= \mathbf{0} & \text{across } \Sigma_1, \dots, \Sigma_N \end{cases} \quad (3)$$

where μ is the piecewise constant function taking the value 1 in Ω^c and μ_j in $\Omega_j, j = 1, \dots, N$. Moreover, we have the following condition at infinity

$$\lim_{\substack{|x| \rightarrow +\infty \\ x \in \mathbb{R}^3}} \mathbf{H}(x) = \mathbf{H}_0 \quad (4)$$

where \mathbf{H}_0 is the applied magnetic field assumed to be constant in strength and direction. By convenience, we denote by $|\cdot|$ either the absolute value of a real number or the euclidean norm of a vector in \mathbb{R}^3 . In (3) and throughout the paper, we will denote by $[u]$ the jump of the quantity u across one of the boundaries Σ_j : $[u] = u|_{\Omega^c} - u|_{\Omega_j}, j = 1, \dots, N$. As well, the quantity \mathbf{n} will refer to the outward unit normal to the boundary Σ_j .

We reformulate problem (3) in terms of the induced magnetic field \mathbf{H}' , such that $\mathbf{H} = \mathbf{H}_0 + \mathbf{H}'$. It is natural to assume that \mathbf{H}' belongs to $\mathbb{L}^2(\mathbb{R}^3)^3$ the Hilbert space of square integrable vector functions. Since \mathbf{H}' is curl free, thanks to Poincaré lemma we can introduce the so-called *scalar magnetic potential* $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ such that

$$\mathbf{H}' = -\nabla \varphi \quad (5)$$

where $\mathbb{W}_0^1(\mathbb{R}^3)$ is the weighted Sobolev space defined by

$$\mathbb{W}_0^1(\mathbb{R}^3) = \left\{ \psi \in \mathcal{D}'(\mathbb{R}^3) ; \frac{\psi}{\sqrt{1+|x|^2}} \in \mathbb{L}^2(\mathbb{R}^3), \nabla \psi \in \mathbb{L}^2(\mathbb{R}^3)^3 \right\}.$$

As outlined in [6] the semi-norm defined by

$$\psi \in \mathbb{W}_0^1(\mathbb{R}^3) \mapsto \left(\int_{\mathbb{R}^3} |\nabla \psi|^2 \, dx \right)^{\frac{1}{2}}$$

is a norm on $\mathbb{W}_0^1(\mathbb{R}^3)$, denoted by $\|\cdot\|_{\mathbb{W}_0^1(\mathbb{R}^3)}$ in the sequel. Moreover, all $\psi \in \mathbb{W}_0^1(\mathbb{R}^3)$ satisfies $[\psi] = 0$ across Σ where Σ denotes any regular surface Σ in \mathbb{R}^3 . The magnetic potential $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ satisfies the following problem deduced from (3)

$$\begin{cases} \Delta \varphi &= 0 & \text{in } \Omega_1, \dots, \Omega_N \text{ and } \Omega^c \\ \left[\mu \frac{\partial \varphi}{\partial n} \right] &= [\mu] \mathbf{H}_0 \cdot \mathbf{n} & \text{across } \Sigma_1, \dots, \Sigma_N \end{cases} \quad (6)$$

We introduce the following normalization: $x_i = R \tilde{x}_i$ for $i = 1, 2, 3$ where \tilde{x}_i denotes the dimensionless i -th coordinate. In the dimensionless coordinates system, problem (6) for the new unknown $\tilde{\varphi}$ defined by $|\mathbf{H}_0| R \tilde{\varphi}(\tilde{x}) = \varphi(R \tilde{x})$ for all $\tilde{x} \in \mathbb{R}^3$, reads

$$\begin{cases} \Delta \tilde{\varphi} &= 0 & \text{in } \tilde{\Omega}_1, \dots, \tilde{\Omega}_N \text{ and } \tilde{\Omega}^c \\ \left[\mu \frac{\partial \tilde{\varphi}}{\partial n} \right] &= [\mu] \frac{\mathbf{H}_0}{|\mathbf{H}_0|} \cdot \mathbf{n} & \text{across } \tilde{\Sigma}_1, \dots, \tilde{\Sigma}_N \end{cases} \quad (7)$$

where $\tilde{\Omega}_j = B(\tilde{c}_j, \tilde{\varepsilon}), \tilde{c}_j = c_j/R, \tilde{\varepsilon} = \varepsilon/R$ and $\tilde{\Omega}^c = \mathbb{R}^3 \setminus \bigcup_{j=1}^N \tilde{\Omega}_j$. We also set $\tilde{\delta} = \delta/R$. Note that the conditions (2) give rise to the conditions

$$2\tilde{\varepsilon} < \tilde{\delta} < \frac{8}{N} < 1. \quad (8)$$

From now on, we will only consider the dimensionless problem (7) and, for convenience, we will drop the tilde \sim symbol introduced to distinguish dimensionless quantities. As well, we

do not write down vectors in bold letters anymore. Thus, we have a magnetostatic problem in the form:

$$\begin{cases} \Delta \varphi &= 0 & \text{in } \Omega_1, \dots, \Omega_N \text{ and } \Omega^c \\ \left[\mu \frac{\partial \varphi}{\partial n} \right] &= [\mu] h & \text{across } \Sigma_1, \dots, \Sigma_N \end{cases} \quad (9)$$

for a given $h \in \mathbb{L}^\infty(\Sigma)$. The weak formulation of problem (9) reads: find $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ such that for all $\psi \in \mathbb{W}_0^1(\mathbb{R}^3)$

$$\int_{\Omega^c} \nabla \varphi \cdot \nabla \psi \, dx + \mu_p \sum_{j=1}^N \int_{\Omega_j} \nabla \varphi \cdot \nabla \psi \, dx = (\mu_p - 1) \sum_{j=1}^N \oint_{\Sigma_j} h \psi \, d\sigma. \quad (10)$$

A direct application of Lax-Milgram theorem proves that problem (10) has a unique solution $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$. Moreover, using φ as a test function in (10), we get

$$\|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)}^2 \leq (\mu_p - 1) \sum_{j=1}^N \|h\|_{\mathbb{L}^\infty(\Sigma_j)} \|\varphi\|_{\mathbb{L}^1(\Sigma_j)} \quad (11)$$

and from the trace inequality (85) given on Appendix A, we deduce that

$$\|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)} \leq A_1 (\mu_p - 1) N \varepsilon^{\frac{3}{2}} \|h\|_{\mathbb{L}^\infty(\Sigma)}, \quad (12)$$

where $\|h\|_{\mathbb{L}^\infty(\Sigma)} = \sup_{j \in \{1, \dots, N\}} \|h\|_{\mathbb{L}^\infty(\Sigma_j)}$ and where $A_1 = \sqrt{4\pi}$. Applying these results in the special case when $h = \frac{H_0}{|H_0|} \cdot n$ whose \mathbb{L}^∞ -norm equals 1, we have proven the following proposition.

Proposition 1. *There exists a unique $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ solution to problem (7). It satisfies*

$$\|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)} \leq A_1 (\mu_p - 1) N \varepsilon^{\frac{3}{2}}, \quad (13)$$

where $A_1 = \sqrt{4\pi}$.

2.2. The one particle case as a reference problem. We consider the following reference problem: find $\varphi_{\text{ref}} \in \mathbb{W}_0^1(\mathbb{R}^3)$ such that

$$\begin{cases} \Delta \varphi_{\text{ref}} &= 0 & \text{in } B(0, \varepsilon) \text{ and } \mathbb{C}\overline{B}(0, \varepsilon) \\ \left[\mu \frac{\partial \varphi_{\text{ref}}}{\partial n} \right] &= [\mu] h & \text{across } S(0, \varepsilon) = \partial B(0, \varepsilon) \end{cases} \quad (14)$$

where $\mu = \mu_p$ in $B(0, \varepsilon)$, $\mu = 1$ in $\mathbb{C}\overline{B}(0, \varepsilon)$ and $h = \frac{H_0}{|H_0|} \cdot n$. For convenience, we consider a reference frame $(0, e_1, e_2, e_3)$ such that H_0 defines the direction of e_3 . With this convention, we have $h = e_3 \cdot n$. Problem (14) admits a unique solution $\varphi_{\text{ref}} \in \mathbb{W}_0^1(\mathbb{R}^3)$. (Indeed, it corresponds to problem (9) in the special case when $N = 1$ and $\Omega_1 = B(0, \varepsilon)$.) In this simple geometrical framework, the solution φ_{ref} can be computed analytically using the separation of variables method in spherical coordinates. Details are given in appendix C. We have

$$\varphi_{\text{ref}}(x) = \begin{cases} \frac{\mu_p - 1}{\mu_p + 2} e_3 \cdot x & \text{in } B(0, \varepsilon) \\ \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x|^3} e_3 \cdot x & \text{in } \mathbb{C}\overline{B}(0, \varepsilon) \end{cases} \quad (15)$$

Moreover, the gradient of φ_{ref} is given by

$$\nabla \varphi_{\text{ref}}(x) = \begin{cases} -\frac{\mu_p - 1}{\mu_p + 2} e_3 & \text{in } B(0, \varepsilon) \\ -\frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x|^3} \left(3(e_3 \cdot x) \frac{x}{|x|^2} - e_3 \right) & \text{in } \mathbb{C}\overline{B}(0, \varepsilon) \end{cases} \quad (16)$$

From (15) and (16) we deduce the following estimates.

FIGURE 2. Notation for the translation of the coordinates system.

Proposition 2. Let φ_{ref} be the solution to problem (14). For all $x \in \mathbb{C}\overline{B}(0, \varepsilon)$, we have

$$|\varphi_{\text{ref}}(x)| \leq \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x|^2} \quad \text{and} \quad |\nabla \varphi_{\text{ref}}(x)| \leq 2 \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x|^3}. \quad (17)$$

Remark 1. Note that for more general shapes of particles, similar estimates can be obtained using classical results of potential theory, see e.g. [11].

For a spherical particle with radius ε centered at position $c_j \in \mathbb{R}^3$, introducing the translation mapping

$$T_{c_j} : x \in \mathbb{R}^3 \mapsto x - c_j \in \mathbb{R}^3, \quad (18)$$

we readily obtain that the function $\varphi_{c_j} = \varphi_{\text{ref}} \circ T_{c_j}$ satisfies

$$\begin{cases} \Delta \varphi_{c_j} = 0 & \text{in } \Omega_j \text{ and } \mathbb{C}\overline{\Omega}_j \\ \left[\mu \frac{\partial \varphi_{c_j}}{\partial n} \right] = [\mu] h & \text{across } \Sigma_j \end{cases} \quad (19)$$

The situation is illustrated in Fig. 2. The solution φ_{c_j} to problem (19) is the magnetic potential induced by the metallic particle Ω_j submitted to the magnetic field H_0 .

3. ACCURACY OF THE NON-INTERACTION ASSUMPTION

3.1. Approximation under the non-interacting assumption. The solution φ to problem (7) can be expressed as

$$\varphi = \sum_{j=1}^N \varphi_{c_j} + \psi. \quad (20)$$

The first term can be interpreted as the scalar magnetic potential induced by the metallic particles under the assumption that they do not interact together. Since outside a particle, the magnetic field induced by the particle decreases as $1/r^3$ where r denotes the distance to the particle center (see Proposition 2), if the particles are at a distance sufficiently large from each other, or if the solid fraction of particles is small, their mutual interaction contribution to the total induced magnetic field can be neglected and it would be reasonable to expect that the approximation $\varphi \approx \sum_{j=1}^N \varphi_{c_j}$ is of good quality. However, if the particles are “not too far” from each other, or if the volume solid fraction of particles is “not too small”, this approximation is not anymore accurate. We want to quantify what “not too far” or “not too small” means by studying the behavior of the correction term ψ .

Proposition 3. The function ψ introduced in (20) belongs to $\mathbb{W}_0^1(\mathbb{R}^3)$ and satisfies

$$\begin{cases} \Delta \psi = 0 & \text{in } \Omega_1, \dots, \Omega_N \text{ and } \Omega^c \\ \left[\mu \frac{\partial \psi}{\partial n} \right] = [\mu] g_0 & \text{across } \Sigma_1, \dots, \Sigma_N \end{cases} \quad (21)$$

where the data g_0 is defined for all $x \in \Sigma_i$, $i \in \{1, \dots, N\}$, by

$$g_0(x) = - \sum_{\substack{j=1 \\ j \neq i}}^N \nabla \varphi_{\text{ref}}(T_{c_j}(x)) \cdot n(x). \quad (22)$$

Proof. By linearity, ψ belongs to $\mathbb{W}_0^1(\mathbb{R}^3)$ and satisfies the Laplace equation in each domain Ω_i , $i \in \{1, \dots, N\}$ and in Ω^c , together with the following interface conditions across Σ_i , $i \in \{1, \dots, N\}$:

$$\left[\mu \frac{\partial \psi}{\partial n} \right] = \left[\mu \frac{\partial \varphi}{\partial n} \right] - \sum_{j=1}^N \left[\mu \frac{\partial \varphi_{c_j}}{\partial n} \right]. \quad (23)$$

Let $i \in \{1, \dots, N\}$. From (7) and (19), we have the following condition at the interface Σ_i

$$\left[\mu \frac{\partial \varphi}{\partial n} \right] = [\mu] h \quad \text{and} \quad \left[\mu \frac{\partial \varphi_{c_i}}{\partial n} \right] = [\mu] h.$$

We deduce that

$$\left[\mu \frac{\partial \psi}{\partial n} \right] = - \sum_{\substack{j=1 \\ j \neq i}}^N \left[\mu \frac{\partial \varphi_{c_j}}{\partial n} \right] \quad \text{across } \Sigma_i. \quad (24)$$

For any $j \in \{1, \dots, N\}$, $j \neq i$, the potential φ_{c_j} solution to problem (19) is continuous in \mathbb{R}^3 and it is regular (regularity \mathcal{C}^∞) everywhere except on the boundary Σ_j . Since for all $j \neq i$ we have $|c_i - c_j| > 2\varepsilon$ (this condition reflects the fact that the particles Ω_i and Ω_j with radius ε do not intersect), the normal derivative $\frac{\partial \varphi_{c_j}}{\partial n}$ is continuous across Σ_i so that (24) also reads

$$\left[\mu \frac{\partial \psi}{\partial n} \right] = -[\mu] \sum_{\substack{j=1 \\ j \neq i}}^N \frac{\partial \varphi_{c_j}}{\partial n} = -[\mu] \left(\sum_{\substack{j=1 \\ j \neq i}}^N \nabla \varphi_{\text{ref}} \circ T_{c_j} \right) \cdot n|_{\Sigma_i}. \quad (25)$$

Proposition 3 is proved. \square

3.2. \mathbb{W}^1 -error estimate under the non-interacting assumption.

Proposition 4. *The source term g_0 defined in (22) is such that*

$$\|g_0\|_{\mathbb{L}^\infty(\Sigma)} \leq 2 \frac{\mu_p - 1}{\mu_p + 2} \left(\frac{2\varepsilon}{\delta} \right)^3 \left(B_3 + 3 \ln \left(\frac{2}{\delta} \right) \right), \quad (26)$$

where $B_3 = 142 + 3 \ln 2 \approx 144.1$.

Proof. The proof relies on Proposition 2. For all $x \in \Sigma_i$, we have

$$|g_0(x)| \leq \sum_{\substack{j=1 \\ j \neq i}}^N |\nabla \varphi_{\text{ref}}(T_{c_j}(x))| \leq 2 \frac{\mu_p - 1}{\mu_p + 2} \sum_{\substack{j=1 \\ j \neq i}}^N \frac{\varepsilon^3}{|T_{c_j}(x)|^3}. \quad (27)$$

The quantity $|T_{c_j}(x)|$ is the distance from the center c_j of the particle Ω_j to the point $x \in \Sigma_i$, see Fig. 3. It is shown in Appendix B, see relation (90), that

$$\sum_{\substack{j=1 \\ j \neq i}}^N \frac{1}{|T_{c_j}(x)|^3} \leq \left(B_3 + 3 \ln \left(\frac{2}{\delta} \right) \right) \left(\frac{2}{\delta} \right)^3. \quad (28)$$

Combining (27) and (28) gives the estimate. \square

Note that problem (21) for ψ has the form of problem (9) for φ for the boundary data $h = g_0$. As a direct consequence of (12) and (26), we have the following result.

FIGURE 3. Effect of the translation of the coordinates system for several particles.

Theorem 1. Let $\Omega_1, \dots, \Omega_N$ be N spherical particles in $B(0, 1) \subset \mathbb{R}^3$, centered respectively at c_j , $j \in \{1, \dots, N\}$, with the same radius $\varepsilon > 0$. Let δ be the minimal distance between two particles as defined in (1). Let $\varphi_{c_j} = \varphi_{\text{ref}} \circ T_{c_j}$ where φ_{ref} is given by (15) be the magnetic potential induced by particle Ω_j taken in isolation from the others. We have

$$\left\| \varphi - \sum_{j=1}^N \varphi_{c_j} \right\|_{\mathbb{W}^1(\mathbb{R}^3)} \leq 2A_1 \frac{(\mu_p - 1)^2}{\mu_p + 2} N \varepsilon^{\frac{3}{2}} \left(\frac{2\varepsilon}{\delta} \right)^3 \left(B_3 + 3 \ln \left(\frac{2}{\delta} \right) \right), \quad (29)$$

where $A_1 = \sqrt{4\pi}$ and $B_3 = 142 + 3 \ln 2 \approx 144.1$.

Remark 2. Note that the bound given in relation (29) that corresponds to an estimate of the first order error term in our asymptotic expansion of the magnetic potential φ is the product of the term $N \varepsilon^{\frac{3}{2}}$ of the order of φ , see estimate (13), and a complementary term comparable to $\left(\frac{2\varepsilon}{\delta}\right)^3 \left(1 + \ln\left(\frac{2}{\delta}\right)\right)$.

3.3. \mathbb{L}^∞ -estimate for the error under the non-interacting assumption. In this subsection, we are interested in providing a point-wise estimate for $\psi = \varphi - \sum_{j=1}^N \varphi_{c_j}$. While the estimate of $\|\psi\|_{\mathbb{W}^1(\mathbb{R}^3)}$ was based on Lax-Milgram theorem, our point-wise estimate for ψ relies on integral representation formula for the Laplacian. Namely, the solution ψ to (21) can be expressed, for all $x \in \Omega^c$, as [5, Thm 2, Chap. XI, p. 120]

$$\psi(x) = -(\mu_p - 1) \sum_{j=1}^N \left(\int_{\Sigma_j} g_0(y) \mathcal{G}(x, y) \, dy - \int_{\Sigma_j} \psi(y) \partial_n \mathcal{G}(x, y) \, dy \right), \quad (30)$$

where \mathcal{G} , the Green kernel of the Laplacian in \mathbb{R}^3 , and its normal derivative on Σ_j , $\partial_n \mathcal{G}$ are given by:

$$\mathcal{G}(x, y) = \frac{1}{4\pi|x - y|}, \quad \partial_n \mathcal{G}(x, y) = \frac{n \cdot (x - y)}{4\pi|x - y|^3}. \quad (31)$$

We deduce from (30), the following estimate for ψ :

$$|\psi(x)| \leq (\mu_p - 1) \sum_{j=1}^N \left(\|g_0\|_{\mathbb{L}^\infty(\Sigma_j)} \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)} + \|\psi\|_{\mathbb{L}^4(\Sigma_j)} \|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_j)} \right), \quad (32)$$

where the choice of the norms involved in (32) are guided by the regularity of Green's kernel. Indeed, it is known, see [5, Rem. 4, Chap. XI, p. 127], that $\mathcal{G}(x, \cdot)$ is integrable on any

boundary Σ_j and that $\partial_n \mathcal{G}(x, \cdot)$ belongs to $\mathbb{L}^p(\Sigma_j)$ for all $p < 2$. Having a $\mathbb{L}^\infty(\Sigma_j)$ -bound on g_0 (see Proposition 3), the way the first integral is bounded is a natural choice. Concerning the second integral, we will use the fact that the Sobolev and trace inequalities implies the following type estimate: $\|\psi\|_{\mathbb{L}^4(\Sigma_j)} \lesssim \|\psi\|_{\mathbb{W}^1(\mathbb{R}^3)}$, and that ψ is already controlled in $\mathbb{W}^1(\mathbb{R}^3)$ -norm (see Theorem 1).

Our point-wise estimate for ψ then relies on the estimates provided in the following Lemma.

Lemma 1. *Let $\Omega_1, \dots, \Omega_N$ be N isolated spherical particles in $B(0, 1) \subset \mathbb{R}^3$, with boundaries $\Sigma_1, \dots, \Sigma_N$, respectively centered at c_j , $j \in \{1, \dots, N\}$, with the same radius ε . Let δ be the minimal distance between two particles as defined in (1). For all $x \in \mathbb{R}^3$, we have*

$$\sum_{j=1}^N \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)} \leq B_1 \left(\frac{2}{\delta}\right)^3 \varepsilon^2 + M_x \varepsilon, \quad (33a)$$

$$\text{and} \quad \sum_{j=1}^N \|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_j)} \leq B_2 \left(\frac{2}{\delta}\right)^3 \varepsilon^{\frac{3}{2}} + M_x A_3 \varepsilon^{\frac{3}{2}}, \quad (33b)$$

where M_x corresponds to the number of particles whose distance at x is less than 2δ (we note that $M_x \leq 64$ and that $M_x \leq N$) and where $B_1 \approx 8.385$, $B_2 \approx 6.611$ and $A_3 \approx 0.3439$ (all the constants introduced are summarized in table 2 page 36).

Proof. Let us start by proving the estimate for $\mathcal{S}_1 = \sum_{j=1}^N \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)}$. For $x \in \Omega^c$ and for $j \in \{1, \dots, N\}$, the quantity $\|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)}$ is the solution to the following problem (see [5, Thm. 2, Chap. XI, p. 120]):

$$\begin{cases} \Delta u = 0 & \text{in } \Omega_j \text{ and } \mathbb{R}^3 \setminus \overline{\Omega_j} \\ [u] = 0 & \text{across } \Sigma_j \\ [\partial_n u] = 1 & \text{across } \Sigma_j \end{cases} \quad (34)$$

The solution to problem (34) can be computed analytically by using the separation of variable method in spherical coordinates. It is found to be:

$$u = \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)} = \begin{cases} \frac{\varepsilon^2}{|x - c_j|} & \text{if } x \in \mathbb{R}^3 \setminus \overline{\Omega_j} \\ \varepsilon & \text{if } x \in \overline{\Omega_j} \end{cases} \quad (35)$$

We split the sum \mathcal{S}_1 into two parts. The first one, denoted $\mathcal{S}_1^{\text{near}}$ in the sequel, corresponds to the indexes j such that the center c_j of the particle Ω_j is at a distance of x smaller than 2δ and the second one, denoted $\mathcal{S}_1^{\text{far}}$ in the sequel, corresponds to the indexes j such that the center c_j is at a distance of x strictly larger than 2δ . Accordingly,

$$\mathcal{S}_1 = \sum_{\substack{i=1 \\ |x-c_i| < 2\delta}}^N \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_i)} + \sum_{\substack{j=1 \\ |x-c_j| \geq 2\delta}}^N \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)} := \mathcal{S}_1^{\text{near}} + \mathcal{S}_1^{\text{far}}. \quad (36)$$

The number of terms in the sum $\mathcal{S}_1^{\text{near}}$ is bounded independently of N . Since $x \in \Omega^c$, this number, denoted M_x , corresponds to the number of disjointed balls of radius 1 that can be contained in a ball of radius 4. By volume consideration, one can show that $M_x \leq 64$. From (35), we deduce that $\mathcal{S}_1^{\text{near}} \leq M_x \varepsilon$.

Using relation (35) and a strategy similar to the one used in Appendix B to show relation (90) or (91), we have

$$\begin{aligned}
\mathcal{S}_1^{\text{far}} &= \sum_{\substack{j=1 \\ |x-c_j| \geq 2\delta}}^N \frac{\varepsilon^2}{|x-c_j|} = \frac{6\varepsilon^2}{\pi\delta^3} \sum_{\substack{j=1 \\ |x-c_j| \geq 2\delta}}^N \int_{B(c_j, \frac{\delta}{2})} \frac{dy}{|x-c_j|} \\
&\leq \frac{6\varepsilon^2}{\pi\delta^3} \sum_{\substack{j=1 \\ |x-c_j| \geq 2\delta}}^N \int_{B(c_j, \frac{\delta}{2})} \frac{dy}{|x-y| - \frac{\delta}{2}} \leq \frac{6\varepsilon^2}{\pi\delta^3} \int_{B(x, 2+\frac{\delta}{2}) \setminus B(x, \frac{3\delta}{2})} \frac{dy}{|x-y| - \frac{\delta}{2}} \\
&\leq \frac{24\varepsilon^2}{\delta^3} \int_{\frac{3\delta}{2}}^{2+\frac{\delta}{2}} \frac{r^2 dr}{r - \frac{\delta}{2}} = \frac{24\varepsilon^2}{\delta^3} \int_{\delta}^2 \frac{(s + \frac{\delta}{2})^2 ds}{s} \leq B_1 \left(\frac{2}{\delta}\right)^3 \varepsilon^2,
\end{aligned}$$

where we have introduced

$$B_1 = \max_{\delta > 0} \int_{\delta}^2 \frac{3(s + \frac{\delta}{2})^2 ds}{s} = 3 \max_{\delta > 0} \left(2 + 2\delta - \frac{3\delta^2}{2} + \frac{\delta^2}{4} \ln \left(\frac{2}{\delta} \right) \right) \approx 8.385.$$

We finally deduce that

$$\mathcal{S}_1 = \mathcal{S}_1^{\text{near}} + \mathcal{S}_1^{\text{far}} \leq B_1 \left(\frac{2}{\delta}\right)^3 \varepsilon^2 + M_x \varepsilon, \quad (37)$$

where the contribution $M_x \varepsilon$ is actually only present if x is at a distance less than 2δ from at least one particle.

The estimate of $\mathcal{S}_2 = \sum_{j=1}^N \|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_j)}$ is obtained in a very similar way. We split the sum over j into two parts according to the distance between the point x and the spheres Σ_j :

$$\mathcal{S}_2 = \sum_{\substack{i=1 \\ |x-c_i| \leq 2\delta}}^N \|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_i)} + \sum_{\substack{j=1 \\ |x-c_j| > 2\delta}}^N \|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_j)} := \mathcal{S}_2^{\text{near}} + \mathcal{S}_2^{\text{far}}. \quad (38)$$

The number of terms in the first sum $\mathcal{S}_2^{\text{near}}$ is, as before, bounded by M_x , independently of N . In order to estimate the quantity $\|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_i)}$ when $|x-c_i| < 2\delta$, we first introduce the projection x^* of x on Σ_i . We note that (see Appendix E)

$$\forall y \in \Sigma_i \quad |\partial_n \mathcal{G}(x, y)| \leq |\partial_n \mathcal{G}(x^*, y)|,$$

and that the quantity $\|\partial_n \mathcal{G}(x^*, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_i)}$ can be explicitly evaluated (see Appendix E for details). We have

$$\|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_i)} \leq A_3 \varepsilon^{\frac{3}{2}} \quad (39)$$

where $A_3 = \|\partial_n \mathcal{G}((1, 0, 0), \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(S^2)} \approx 0.3439$. (The result is proven in Appendix E for a ball of radius 1 but by dilation one easily reveals the factor $\varepsilon^{\frac{3}{2}}$). Finally, we obtain

$$\mathcal{S}_2^{\text{near}} \leq M_x A_3 \varepsilon^{\frac{3}{2}}.$$

Let us now consider the sum $\mathcal{S}_2^{\text{far}}$ in (38) over the indexes j such that x is at a distance larger than 2δ from the center c_j of the particle Ω_j . For x such that $|x-c_i| > 2\delta$ and for $y \in \Sigma_j$, we have

$$|x-y| \geq |x-c_i| - \varepsilon \geq \frac{2\delta - \varepsilon}{2\delta} |x-c_j| > \frac{3}{4} |x-c_j|$$

so that

$$\|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_j)} \leq \frac{1}{4\pi} \left(\oint_{\Sigma_j} \frac{dy}{|x-y|^{\frac{8}{3}}} \right)^{\frac{3}{4}} \leq \frac{4}{9\pi} \left(\oint_{\Sigma_j} \frac{dy}{|x-c_j|^{\frac{8}{3}}} \right)^{\frac{3}{4}} = \frac{4}{9\pi} (4\pi\varepsilon^2)^{\frac{3}{4}} \frac{1}{|x-c_j|^2}.$$

Summing over j and using the same strategy as in the case of the sum $\mathcal{S}_1^{\text{far}}$, we deduce that

$$\mathcal{S}_2^{\text{far}} \leq B_2 \left(\frac{2}{\delta}\right)^3 \varepsilon^{\frac{3}{2}}$$

where $B_2 = \frac{\sqrt{2}}{3\pi^{\frac{1}{4}}} \max_{\delta>0} (8 - 6\delta - \delta^2 + 8\delta \ln(\frac{2}{\delta})) \approx 6.611$. We finally deduce that

$$\mathcal{S}_2 = \mathcal{S}_2^{\text{near}} + \mathcal{S}_2^{\text{far}} \leq B_2 \left(\frac{2}{\delta}\right)^3 \varepsilon^{\frac{3}{2}} + M_x A_3 \varepsilon^{\frac{3}{2}},$$

where the contribution $M_x A_3 \varepsilon^{\frac{3}{2}}$ is only present if x is at a distance smaller than 2δ to any ball. \square

We are now in position to state the following point-wise estimate for ψ under the same assumptions as for theorem 1.

Theorem 2. *Let $\Omega_1, \dots, \Omega_N$ be N isolated spherical particles in $B(0,1) \subset \mathbb{R}^3$, centered respectively at c_j , $j \in \{1, \dots, N\}$, with the same radius ε . Let δ be the minimal distance between two particles as defined in (1). Let $\varphi_{c_j} = \varphi_{\text{ref}} \circ T_{c_j}$ where φ_{ref} is given by (15) be the magnetic potential induced by particle Ω_j taken in isolation from the others. For all $x \in \Omega^c$, we have*

$$\begin{aligned} \left| \varphi(x) - \sum_{j=1}^N \varphi_{c_j}(x) \right| \leq & 2 \frac{(\mu_p - 1)^2}{\mu_p + 2} \left(\frac{2\varepsilon}{\delta}\right)^3 \varepsilon \left(B_3 + 3 \ln\left(\frac{2}{\delta}\right) \right) \left(B_1 \left(\frac{2}{\delta}\right)^3 \varepsilon + M_x \right. \\ & \left. + A_1 A_2 (\mu_p - 1) N \varepsilon^2 \left(B_2 \left(\frac{2}{\delta}\right)^3 + M_x A_3 \right) \right), \end{aligned} \quad (40)$$

where M_x corresponds to the number of particles whose distance at x is less than 2δ (we note that $M_x \leq 64$ and that $M_x \leq N$). Note that all the constants have been explicitly estimated and are summarized in table 2 on p. 36.

Proof. From (32), $\psi = \varphi - \sum_{j=1}^N \varphi_{c_j}$ satisfies for all $x \in \Omega^c$,

$$|\psi(x)| \leq (\mu_p - 1) \sum_{j=1}^N \left(\|g_0\|_{\mathbb{L}^\infty(\Sigma_j)} \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)} + \|\psi\|_{\mathbb{L}^4(\Sigma_j)} \|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_j)} \right). \quad (41)$$

From Lemma 1, we have the estimates

$$\begin{aligned} \sum_{j=1}^N \|\mathcal{G}(x, \cdot)\|_{\mathbb{L}^1(\Sigma_j)} & \leq B_1 \left(\frac{2}{\delta}\right)^3 \varepsilon^2 + M_x \varepsilon, \\ \sum_{j=1}^N \|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(\Sigma_j)} & \leq B_2 \left(\frac{2}{\delta}\right)^3 \varepsilon^{\frac{3}{2}} + M_x A_3 \varepsilon^{\frac{3}{2}}. \end{aligned}$$

It remains to estimate $\|\psi\|_{\mathbb{L}^4(\Sigma_j)}$. From trace theory and Sobolev embeddings, it is possible to obtain the following inequality (see Appendix A):

$$\|\psi\|_{\mathbb{L}^4(\Sigma_j)} \leq A_2 \|\psi\|_{\mathbb{W}^1(\mathbb{R}^3)}, \quad (42)$$

for all $j \in \{1, \dots, N\}$ with $A_2 = \frac{2}{3^{\frac{3}{8}} \sqrt{\pi}}$. Since ψ is solution to problem (21) which differs from problem (9) only by the boundary data h , ψ satisfies the estimate (12) with h replaced by g_0 , i.e. for all $j \in \{1, \dots, N\}$, we have

$$\|\psi\|_{\mathbb{L}^4(\Sigma_j)} \leq A_1 A_2 (\mu_p - 1) N \varepsilon^{\frac{3}{2}} \|g_0\|_{\mathbb{L}^\infty(\Sigma)}. \quad (43)$$

It follows from (41) that

$$|\psi(x)| \leq (\mu_p - 1) \|g_0\|_{\infty} \varepsilon \left(B_1 \left(\frac{2}{\delta}\right)^3 \varepsilon + M_x + A_1 A_2 (\mu_p - 1) N \varepsilon^2 \left(B_2 \left(\frac{2}{\delta}\right)^3 + M_x A_3 \right) \right).$$

We conclude the proof using the estimate of $\|g_0\|_\infty$ provided in proposition 4. \square

Remark 3. Both Theorem 1 and Theorem 2 can be interpreted as follows. In the extreme case when we consider only two particles, the error made by adding the contribution to the magnetic potential of the two particles assuming no mutual influence, is roughly speaking proportional to the cube of the ratio of the particles radius to the distance separating the two particles. In the other extreme case when considering a very large number of particles able to fill the area of interest completely and evenly, the ratio $\frac{\varepsilon^3}{\delta^3}$ is proportional to the volume fraction of particles. Thus, when the volume fraction is low, that is to say when the particles are spaced at a fairly large distance from each other, computing the magnetic potential by neglecting magnetic field reciprocal interactions between particles gives a quite accurate approximation.

4. TAKING INTO ACCOUNT PAIRWISE INTERACTIONS

4.1. Reference problem for the pairwise interactions. When the approximation $\varphi \approx \sum_{j=1}^N \varphi_{c_j}$ is not accurate enough, one can compute the error term ψ in (20) using the same idea as the one introduced in the previous section for the magnetic potential φ , that is to say by expanding ψ as

$$\psi = \sum_{j=1}^N \sum_{\substack{k=1 \\ k \neq j}}^N \psi_{c_k, c_j} + \chi \quad (44)$$

where ψ_{c_k, c_j} , $j, k = 1, \dots, N$, $k \neq j$, are found to satisfy

$$\begin{cases} \Delta \psi_{c_k, c_j} = 0 & \text{in } \Omega_j \text{ and } \mathbb{C}\overline{\Omega}_j \\ \left[\mu \frac{\partial \psi_{c_k, c_j}}{\partial n} \right] = [\mu] (\nabla \varphi_{\text{ref}} \circ T_{c_k}) \cdot n & \text{across } \Sigma_j \end{cases} \quad (45)$$

It should be noted that each couple of functions $(\psi_{c_j, c_k}, \psi_{c_k, c_j})$ is related to the potential created by the two particles Ω_j and Ω_k . Namely, the sum $\varphi_{c_j} + \varphi_{c_k} + \psi_{c_j, c_k} + \psi_{c_k, c_j}$ corresponds to the potential created by the two particles Ω_j and Ω_k , without taking into account the other particles.

The solution ψ_{c_k, c_j} to problem (45) can be expressed as

$$\psi_{c_k, c_j} = \psi_{c_k - c_j, 0} \circ T_{c_j} \quad (46)$$

where $\psi_{c_k - c_j, 0} \in \mathbb{W}_0^1(\mathbb{R}^3)$ is solution to the following reference problem for $u = c_k - c_j$

$$\begin{cases} \Delta \psi_{\text{ref}}^u = 0 & \text{in } B(0, \varepsilon) \text{ and } \mathbb{C}\overline{B}(0, \varepsilon) \\ \left[\mu \frac{\partial \psi_{\text{ref}}^u}{\partial n} \right] = -[\mu] g^u & \text{across } S(0, \varepsilon). \end{cases} \quad (47)$$

where $g^u = -(\nabla \varphi_{\text{ref}} \circ T_u) \cdot n$.

Note that when studying the non-interaction assumption in the last section, the reference problem was independent of the ball center: for symmetry reasons, by a translation one could consider a ball centered at origin. When considering pairwise interaction, there is no more symmetry and the reference problem depends on the relative position of the two balls.

The objective now is to obtain estimates for ψ_{ref}^u similar to the ones obtained for φ_{ref} in proposition 2. The main difficulties are that we do not have an explicit expression for ψ_{ref}^u as it was the case for φ_{ref} and that there is no longer invariance by rotation of the solution to problem (47) as it was the case for problem (14).

4.2. **Explicit solution to the second reference problems.** Since ψ_{ref}^u satisfies the Laplace equation, it can be expanded in spherical coordinates (r, θ, η) as

$$\psi_{\text{ref}}^u(r, \theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \left(\alpha_{\ell}^m r^{\ell} + \beta_{\ell}^m \frac{1}{r^{\ell+1}} \right) Y_{\ell}^m(\theta, \eta) \quad (48)$$

where α_{ℓ}^m and β_{ℓ}^m are complex numbers to be determined and Y_{ℓ}^m denotes the Spherical Surface Harmonic function of degree ℓ and order m [21].

The following lemma specifies the expression of the series expansion of ψ_{ref}^u . This expression is purely formal at this stage. Convergence of the series expansion will be proved in proposition 5.

Lemma 2. *The Spherical Surface Harmonics series expansion of ψ_{ref}^u reads*

$$\psi_{\text{ref}}^u(r, \theta, \eta) = \begin{cases} \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \frac{\mu_p - 1}{(\mu_p + 1)\ell + 1} \frac{r^{\ell}}{\varepsilon^{\ell-1}} g_{\ell}^m Y_{\ell}^m(\theta, \eta) & \text{if } r < \varepsilon \\ \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \frac{\mu_p - 1}{(\mu_p + 1)\ell + 1} \frac{\varepsilon^{2+\ell}}{r^{1+\ell}} g_{\ell}^m Y_{\ell}^m(\theta, \eta) & \text{if } r \geq \varepsilon \end{cases}$$

where $g_{\ell}^m = \int_0^{2\pi} \left(\int_0^{\pi} g^u(\theta, \eta) \overline{Y_{\ell}^m(\theta, \eta)} \sin(\theta) d\theta \right) d\eta$ are the coefficients of the Spherical Surface Harmonics series expansion of the source term g^u introduced in (47).

Proof. We consider the formal series expansion (48) of the solution ψ_{ref}^u to problem (47). Because the magnetic potential must be bounded for $r = 0$, it reads in $\overline{B}(0, \varepsilon)$

$$\psi_{\text{ref}}^u(r, \theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \alpha_{\ell}^m r^{\ell} Y_{\ell}^m(\theta, \eta). \quad (49)$$

Moreover, because the magnetic potential must tend to zero at infinity, we have in $\mathbb{C}\overline{B}(0, \varepsilon)$

$$\psi_{\text{ref}}^u(r, \theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \beta_{\ell}^m \frac{1}{r^{\ell+1}} Y_{\ell}^m(\theta, \eta). \quad (50)$$

The constants α_{ℓ}^m and β_{ℓ}^m are determined by the conditions across $S(0, \varepsilon)$. The continuity of the solution ψ_{ref}^u across the sphere $S(0, \varepsilon)$ implies

$$\forall \ell \in \mathbb{N} \quad \forall m \in \{-\ell, \dots, \ell\} \quad \alpha_{\ell}^m = \frac{\beta_{\ell}^m}{\varepsilon^{2\ell+1}}. \quad (51)$$

Let us examine the condition on the normal derivative in (47). From (16), we have for all $x \in S(0, \varepsilon)$

$$g^u(x) = -\frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x - u|^5} \left(3(e_3 \cdot (x - u)) ((x - u) \cdot n) - (e_3 \cdot n) ((x - u) \cdot (x - u)) \right). \quad (52)$$

This function belongs to $\mathcal{C}^{\infty}(S(0, \varepsilon))$ and it can be expanded as a linear combination of Spherical Surface Harmonics as

$$g^u(\theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} g_{\ell}^m Y_{\ell}^m(\theta, \eta) \quad (53)$$

where

$$g_{\ell}^m = \int_0^{2\pi} \left(\int_0^{\pi} g^u(\theta, \eta) \overline{Y_{\ell}^m(\theta, \eta)} \sin(\theta) d\theta \right) d\eta. \quad (54)$$

Thus, the interface condition in (45) is found to give rise to the relations

$$\forall \ell \in \mathbb{N} \quad \forall m \in \{-\ell, \dots, \ell\} \quad \mu_p \alpha_{\ell}^m \ell \varepsilon^{\ell-1} + (\ell + 1) \frac{\beta_{\ell}^m}{\varepsilon^{\ell+2}} = (\mu_p - 1) g_{\ell}^m.$$

From (51), it follows that

$$\forall \ell \in \mathbb{N} \quad \forall m \in \{-\ell, \dots, \ell\} \quad \beta_\ell^m = \frac{\mu_p - 1}{(\mu_p + 1)\ell + 1} \varepsilon^{\ell+2} g_\ell^m. \quad (55)$$

□

According to Lemma 2, in order to estimate the behavior of the solution ψ_{ref}^u to the reference problem (47), we have to control the coefficients g_ℓ^m . This is the subject of the following lemma where the notation Δ_s refers to the Laplace-Beltrami operator on the sphere

$$\Delta_s = \frac{1}{\sin(\theta)} \partial_\theta (\sin(\theta) \partial_\theta) + \frac{1}{\sin^2(\theta)} \partial_\eta^2.$$

For all integer $p \geq 1$, we set $\Delta_s^p = \Delta_s \circ \dots \circ \Delta_s$ (p times) and by convention Δ_s^0 is the identity. For convenience, we also introduce the gradient operator on the sphere :

$$\nabla_s = \begin{pmatrix} \frac{\partial}{\partial \theta} \\ \frac{1}{\sin(\theta)} \frac{\partial}{\partial \eta} \end{pmatrix}$$

Lemma 3. *Coefficients g_ℓ^m for $\ell \in \mathbb{N}, m \in \{-\ell, \dots, \ell\}$ in the spherical harmonic expansion of g^u defined in (53)–(54) satisfy $g_0^0 = 0$ and for any choice of $p \in \mathbb{N}$*

$$\forall \ell \in \mathbb{N} \setminus \{0\} \quad \forall m \in \{-\ell, \dots, \ell\} \quad |g_\ell^m| \leq \frac{\sqrt{4\pi}}{(\ell(\ell+1))^p} \|\Delta_s^p g^u\|_\infty,$$

with

$$\|g^u\|_\infty \leq 4 \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{(|u| - \varepsilon)^3}, \quad (56a)$$

$$\|\Delta_s g^u\|_\infty \leq \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{(|u| - \varepsilon)^5} (450\varepsilon^2 + 139\varepsilon|u| + 8|u|^2). \quad (56b)$$

Proof. Let us first show that $g_0^0 = 0$. From (54), we have

$$g_0^0 = -\frac{1}{\sqrt{2\pi}} \oint_{S(0,\varepsilon)} \frac{\partial \varphi_{\text{ref}}}{\partial n}(x - u) \, d\sigma_x = -\frac{1}{\sqrt{2\pi}} \oint_{u+S(0,\varepsilon)} \frac{\partial \varphi_{\text{ref}}}{\partial n}(y) \, d\sigma_y.$$

It follows from Stokes' formula that

$$g_0^0 = -\frac{1}{2\sqrt{\pi}} \int_{u+B(0,\varepsilon)} \Delta \varphi_{\text{ref}}(y) \, dy = 0.$$

Let us now consider the estimates of g_ℓ^m for $\ell \geq 1$. To highlight the decrease in coefficients with respect to ℓ , the idea is to use the fact that the elements Y_ℓ^m are eigenfunctions to the laplacian. More precisely, we have $\Delta_s Y_\ell^m = -\ell(\ell+1) Y_\ell^m$. It follows from (54) that

$$g_\ell^m = -\frac{1}{\ell(\ell+1)} \int_0^{2\pi} \int_0^\pi g^u(\theta, \eta) \Delta_s \overline{Y_\ell^m}(\theta, \eta) \sin(\theta) \, d\theta \, d\eta.$$

Since $g^u \in C^\infty(S(0, \varepsilon))$, using Green's formula, we have

$$g_\ell^m = -\frac{1}{\ell(\ell+1)} \int_0^{2\pi} \int_0^\pi \Delta_s g^u(\theta, \eta) \overline{Y_\ell^m}(\theta, \eta) \sin(\theta) \, d\theta \, d\eta.$$

Then, repeated use of Green's formula $p-1$ more times yields

$$g_\ell^m = \frac{(-1)^p}{(\ell(\ell+1))^p} \int_0^{2\pi} \int_0^\pi \Delta_s^p g^u(\theta, \eta) \overline{Y_\ell^m}(\theta, \eta) \sin(\theta) \, d\theta \, d\eta.$$

It follows that

$$\begin{aligned}
|g_\ell^m| &\leq \frac{1}{(\ell(\ell+1))^p} \int_0^{2\pi} \left(\int_0^\pi |\Delta_s^p g^u(\theta, \eta)| |\overline{Y_\ell^m}(\theta, \eta)| \sin(\theta) \, d\theta \right) d\eta \\
&\leq \frac{1}{(\ell(\ell+1))^p} \|\Delta_s^p g^u\|_\infty \int_0^{2\pi} \left(\int_0^\pi |Y_\ell^m(\theta, \eta)| \sin(\theta) \, d\theta \right) d\eta \\
&\leq \frac{\sqrt{4\pi}}{(\ell(\ell+1))^p} \|\Delta_s^p g^u\|_\infty.
\end{aligned}$$

This complete the first part of the proof. It remains to show the two estimates (56). From (52), we have for all $x \in S(0, \varepsilon)$

$$|g^u(x)| \leq 4 \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x - u|^3}.$$

The estimate (56a) follows from the inequality: $|x - u| \geq |u| - |x| = |u| - \varepsilon$.

In order to obtain the estimate for $\|\Delta_s g^u\|_\infty$, we proceed as follows. We have

$$g^u(x) = -\frac{\mu_p - 1}{\mu_p + 2} \left(3 \frac{h^{\tilde{u}}(\tilde{x})}{|\tilde{x} - \tilde{u}|^5} - \frac{(e_3 \cdot n)}{|\tilde{x} - \tilde{u}|^3} \right), \quad (57)$$

where we have set $\tilde{x} = x/\varepsilon$, $\tilde{u} = u/\varepsilon$ and

$$h^{\tilde{u}}(\tilde{x}) = (e_3 \cdot (\tilde{x} - \tilde{u})) ((\tilde{x} - \tilde{u}) \cdot n).$$

For $p \in \mathbb{N}$, $p \geq 1$, we set $\forall \tilde{x} \in S^2$ and $\forall \tilde{u} \notin S^2$

$$G_p(\tilde{x}, \tilde{u}) = \frac{1}{|\tilde{x} - \tilde{u}|^p}.$$

A simple, yet cumbersome, direct calculation shows that

$$\Delta_s G_p(\tilde{x}, \tilde{u}) = p(p+2) |J_s(\tilde{x}) \tilde{u}|^2 G_{p+4}(\tilde{x}, \tilde{u}) - 2p(1 + (\tilde{x} \cdot (\tilde{u} - \tilde{x}))) G_{p+2}(\tilde{x}, \tilde{u})$$

where $J_s(\tilde{x})$ denotes the following 2×3 matrix

$$J_s(\tilde{x}) = \begin{pmatrix} \cos(\theta) \cos(\eta) & \cos(\theta) \sin(\eta) & -\sin(\eta) \\ -\sin(\eta) & \cos(\eta) & 0 \end{pmatrix} = \nabla_s \tilde{x}.$$

Moreover, we have

$$\nabla_s G_p(\tilde{x}, \tilde{u}) = p (J_s(\tilde{x}) \tilde{u}) G_{p+2}(\tilde{x}, \tilde{u}).$$

Note that $J_s(\tilde{x}) \tilde{u} = J_s(\tilde{x}) (\tilde{u} - \tilde{x})$ and

$$|J_s(\tilde{x}) \tilde{u}| \leq \sqrt{2} |\tilde{x} - \tilde{u}|.$$

Therefore,

$$|\Delta_s G_p(\tilde{x}, \tilde{u})| \leq 2p(p+3) G_{p+2}(\tilde{x}, \tilde{u}) + 2p G_{p+1}(\tilde{x}, \tilde{u}) \quad (58)$$

$$|\nabla_s G_p(\tilde{x}, \tilde{u})| \leq \sqrt{2} p G_{p+1}(\tilde{x}, \tilde{u}). \quad (59)$$

Another direct calculation shows that

$$\Delta_s h^{\tilde{u}}(\tilde{x}) = 2(1 - n \cdot (\tilde{x} - \tilde{u})) ((\tilde{x} - \tilde{u}) \cdot e_3) - 2(\tilde{x} \cdot e_3) ((\tilde{x} - \tilde{u}) \cdot n) + 2(\partial_\theta \tilde{x} \cdot e_3) (\partial_\theta x \cdot (\tilde{x} - \tilde{u}))$$

and

$$\nabla_s h^{\tilde{u}}(\tilde{x}) = ((\tilde{x} - \tilde{u}) \cdot n) (J_s(\tilde{x}) e_3) - ((\tilde{x} - \tilde{u}) \cdot e_3) (J_s(\tilde{x}) \tilde{u}).$$

Because $|\tilde{x}| = |\partial_\theta \tilde{x}| = |\partial_\eta \tilde{x}| = 1$, we have the estimates

$$|h^{\tilde{u}}(\tilde{x})| \leq |\tilde{x} - \tilde{u}|^2 \quad (60)$$

$$|\Delta_s h^{\tilde{u}}(\tilde{x})| \leq 2 |\tilde{x} - \tilde{u}|^2 + 6 |\tilde{x} - \tilde{u}| \quad (61)$$

$$|\nabla_s h^{\tilde{u}}(\tilde{x})| \leq \sqrt{2} |\tilde{x} - \tilde{u}|^2 + |\tilde{x} - \tilde{u}|. \quad (62)$$

Now, using the differential calculus formula

$$\Delta_s(f \times g) = f \Delta_s g + g \Delta_s f + 2 \nabla_s f \cdot \nabla_s g$$

we deduce that

$$\begin{aligned} \Delta_s g^u(x) = & -\frac{\mu_p - 1}{\mu_p + 2} \left(3h^{\tilde{u}}(\tilde{x}) \Delta_s G_5(\tilde{x}, \tilde{u}) + 3G_5(\tilde{x}, \tilde{u}) \Delta_s h^{\tilde{u}}(\tilde{x}) + 6\nabla_s G_5(\tilde{x}, \tilde{u}) \cdot \nabla_s h^{\tilde{u}}(\tilde{x}) \right. \\ & \left. - (e_3 \cdot n) \Delta_s G_3(\tilde{x}, \tilde{u}) - G_3(\tilde{x}, \tilde{u}) \Delta_s (e_3 \cdot n) - 2\nabla_s G_3(\tilde{x}, \tilde{u}) \cdot \nabla_s (e_3 \cdot n) \right). \end{aligned}$$

To get the estimate for $\Delta_s g^u(x)$ we proceed by estimating each term involved in the preceding expression:

$$\begin{aligned} |\Delta_s g^u(x)| & \leq \frac{\mu_p - 1}{\mu_p + 2} \left(8G_3(\tilde{x}, \tilde{u}) + 6(19 + \sqrt{2})G_4(\tilde{x}, \tilde{u}) + 6(46 + 5\sqrt{2})G_5(\tilde{x}, \tilde{u}) \right) \\ & \leq \frac{\mu_p - 1}{\mu_p + 2} \frac{1}{|\tilde{x} - \tilde{u}|^5} \left(8|\tilde{x} - \tilde{u}|^2 + 123|\tilde{x} - \tilde{u}| + 219 \right) \\ & = \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x - u|^5} \left(8|x - u|^2 + 123\varepsilon|x - u| + 219\varepsilon^2 \right) \end{aligned}$$

From the inequalities $|x - u| \leq |x| + |u|$ and $|x - u| \geq |u| - |x| = |u| - \varepsilon$, we finally obtain

$$|\Delta_s g^u(x)| \leq \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{(|u| - \varepsilon)^5} \left(450\varepsilon^2 + 139\varepsilon|u| + 8|u|^2 \right). \quad (63)$$

□

We are now in position to prove convergence of the series expansion for ψ_{ref}^u introduced in lemma 2.

Proposition 5. *The series (50) where β_ℓ^m , $\ell \in \mathbb{N}$, $m \in \{-\ell, \dots, \ell\}$, is defined in (55) converges uniformly on $\mathbb{C}\bar{B}(0, \varepsilon)$.*

The series (49) where α_ℓ^m , $\ell \in \mathbb{N}$, $m \in \{-\ell, \dots, \ell\}$, is defined in (51) converges uniformly on $B(0, \varepsilon)$.

Proof. Let $a_\ell(r, \theta, \eta) = \sum_{m=-\ell}^{\ell} \alpha_\ell^m r^\ell Y_\ell^m(\theta, \eta)$ be the coefficient of rank ℓ of the series (49). From (51) and (55), we have

$$a_\ell(r, \theta, \eta) = \frac{(\mu_p - 1)\varepsilon}{(\mu_p + 1)\ell + 1} \left(\frac{r}{\varepsilon} \right)^\ell \sum_{m=-\ell}^{\ell} g_\ell^m Y_\ell^m(\theta, \eta).$$

It follows from lemma 3 (considered with $p = 1$) that

$$|a_\ell(r, \theta, \eta)| \leq \frac{\sqrt{4\pi}}{\ell(\ell + 1)} \|\Delta_s g^u\|_\infty \frac{(\mu_p - 1)\varepsilon}{(\mu_p + 1)\ell + 1} \left(\frac{r}{\varepsilon} \right)^\ell \sum_{m=-\ell}^{\ell} |Y_\ell^m(\theta, \eta)|. \quad (64)$$

Using the following estimate for Spherical Surface Harmonics (see Appendix D for a proof)

$$\sum_{m=-\ell}^{\ell} |Y_\ell^m(\theta, \eta)| \leq \frac{3\sqrt{3}}{\sqrt{4\pi}} \ell^{\frac{3}{2}} \quad (65)$$

we conclude that $\sum_{\ell \in \mathbb{N}} a_\ell(r, \theta, \eta)$ is uniformly convergent on $B(0, \varepsilon)$.

Similarly, let $b_\ell(r, \theta, \eta) = \sum_{m=-\ell}^{\ell} \beta_\ell^m \frac{1}{r^{\ell+1}} Y_\ell^m(\theta, \eta)$ be the coefficient of rank ℓ of the series (50). From (55), we have

$$b_\ell(r, \theta, \eta) = \frac{(\mu_p - 1)\varepsilon}{(\mu_p + 1)\ell + 1} \left(\frac{\varepsilon}{r} \right)^{\ell+1} \sum_{m=-\ell}^{\ell} g_\ell^m Y_\ell^m(\theta, \eta). \quad (66)$$

From lemma 3 and from (65), we deduce that

$$|b_\ell(r, \theta, \eta)| \leq \frac{(\mu_p - 1)\varepsilon}{(\mu_p + 1)\ell + 1} \|\Delta_s g^u\|_{\infty, S(0, \varepsilon)} \frac{3\sqrt{3} \ell^{\frac{3}{2}}}{\ell(\ell + 1)} \left(\frac{\varepsilon}{r} \right)^{\ell+1} \quad (67)$$

and we conclude that the function series $\sum_{\ell \in \mathbb{N}} b_\ell(r, \theta, \eta)$ converges uniformly on $\mathbb{C}\bar{B}(0, \varepsilon)$. □

Finally, we are in position to prove the following result for ψ_{ref}^u which is the analogue of proposition 2 for φ_{ref} .

Proposition 6. *Let ψ_{ref}^u be the solution to problem (47). For all $x \in \overline{\mathbb{C}B}(0, \varepsilon)$, we have*

$$\begin{aligned} |\psi_{\text{ref}}^u(x)| &\leq 12\sqrt{3} \lambda_p \frac{\varepsilon^3}{(|u| - \varepsilon)^3} \frac{\varepsilon^2}{|x|} \text{Li}_{-\frac{1}{2}}\left(\frac{\varepsilon}{|x|}\right) \\ |\nabla \psi_{\text{ref}}^u(x)| &\leq A_4 \lambda_p \frac{\varepsilon^3}{(|u| - \varepsilon)^3} \frac{\varepsilon^2}{|x|^2} \text{Li}_{-\frac{3}{2}}\left(\frac{\varepsilon}{|x|}\right) \end{aligned} \quad (68)$$

where $\lambda_p := \frac{(\mu_p - 1)^2}{(\mu_p + 1)(\mu_p + 2)} \in [0, 1]$ and $\text{Li}_s(z)$ refers to the Polylogarithm function of order s (also called Jonquière's function). Moreover, the constant A_4 is such that $A_4 \approx 59.93$.

Proof. The estimate of $\psi_{\text{ref}}^u(x)$ is deduced from the Spherical Surface Harmonic series expansion given in Lemma 2 for $r \geq \varepsilon$ combined with the estimate of the coefficients g_ℓ^m given in lemma 3 for $p = 0$ and with the estimate (65) for the Spherical Surface Harmonics.

Let us consider the estimate of $\nabla \psi_{\text{ref}}^u(x)$. In the spherical coordinate basis, we have

$$|\nabla \psi_{\text{ref}}^u(x)|^2 = |\partial_r \psi_{\text{ref}}^u(r, \theta, \eta)|^2 + \left| \frac{1}{r} \partial_\theta \psi_{\text{ref}}^u(r, \theta, \eta) \right|^2 + \left| \frac{1}{r \sin(\theta)} \partial_\eta \psi_{\text{ref}}^u(r, \theta, \eta) \right|^2. \quad (69)$$

Since $\psi_{\text{ref}}^u(r, \theta, \eta) = \sum_{\ell=1}^{+\infty} \sum_{m=-\ell}^{\ell} \beta_\ell^m \frac{1}{r^{\ell+1}} Y_\ell^m(\theta, \eta)$ in $\overline{\mathbb{C}B}(0, \varepsilon)$, we deduce that

$$\partial_r \psi_{\text{ref}}^u(r, \theta, \eta) = - \sum_{\ell=1}^{+\infty} \sum_{m=-\ell}^{\ell} \beta_\ell^m \frac{\ell+1}{r^{\ell+2}} Y_\ell^m(\theta, \eta)$$

and an estimate for $\partial_r \psi_{\text{ref}}^u$ can be obtained in exactly the same way as for ψ_{ref}^u . Namely, using

- estimate (55) for coefficients β_ℓ^m
- estimate of the coefficients g_ℓ^m given in lemma 3 considered with $p = 0$

$$|g_\ell^m| \leq 4\sqrt{4\pi} \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{(|u| - \varepsilon)^3} \quad (70)$$

- estimate (65) on the Spherical Surface Harmonic functions Y_ℓ^m

we find that

$$|\partial_r \psi_{\text{ref}}^u(r, \theta, \eta)| \leq 24\sqrt{3} \lambda_p \frac{\varepsilon^3}{(|u| - \varepsilon)^3} \frac{\varepsilon^2}{r^2} \text{Li}_{-\frac{3}{2}}\left(\frac{\varepsilon}{r}\right). \quad (71)$$

Let us consider the second component of $\nabla \psi_{\text{ref}}^u$ given by

$$\frac{1}{r} \partial_\theta \psi_{\text{ref}}^u(r, \theta, \eta) = \sum_{\ell=1}^{+\infty} \sum_{m=-\ell}^{\ell} \beta_\ell^m \frac{1}{r^{\ell+2}} \partial_\theta Y_\ell^m(\theta, \eta).$$

Here again, using estimate (55) for coefficients β_ℓ^m combined with the estimate g_ℓ^m given in lemma 3 considered with $p = 0$ and the estimate of $\sum_{m=-\ell}^{\ell} |\partial_\theta Y_\ell^m(\theta, \eta)|$ given by (117) in Appendix D, we get

$$\left| \frac{1}{r} \partial_\theta \psi_{\text{ref}}^u(r, \theta, \eta) \right| \leq 4\sqrt{6}(1 + \pi) \lambda_p \frac{\varepsilon^3}{(|u| - \varepsilon)^3} \frac{\varepsilon^2}{r^2} \text{Li}_{-\frac{3}{2}}\left(\frac{\varepsilon}{r}\right). \quad (72)$$

The third component of $\nabla \psi_{\text{ref}}^u$ is given by

$$\frac{1}{r \sin(\theta)} \partial_\eta \psi_{\text{ref}}^u(r, \theta, \eta) = \sum_{\ell=1}^{+\infty} \sum_{m=-\ell}^{\ell} \beta_\ell^m \frac{1}{r^{\ell+2}} \frac{1}{\sin(\theta)} \partial_\eta Y_\ell^m(\theta, \eta).$$

Proceeding as before using now the estimate of $\sum_{m=-\ell}^{\ell} \left| \frac{1}{\sin(\theta)} \partial_\eta Y_\ell^m(\theta, \eta) \right|$ given by (118) in Appendix D, we get

$$\left| \frac{1}{r \sin(\theta)} \partial_\eta \psi_{\text{ref}}^u(r, \theta, \eta) \right| \leq 6\sqrt{6} \lambda_p \frac{\varepsilon^3}{(|u| - \varepsilon)^3} \frac{\varepsilon^2}{r^2} \text{Li}_{-\frac{3}{2}}\left(\frac{\varepsilon}{r}\right). \quad (73)$$

Finally, combining (71), (72) and (73) together with (69), we conclude that

$$|\nabla \psi_{\text{ref}}^u(x)| \leq A_4 \lambda_p \frac{\varepsilon^3}{(|u| - \varepsilon)^3} \frac{\varepsilon^2}{|x|^2} \text{Li}_{-\frac{3}{2}}\left(\frac{\varepsilon}{|x|}\right), \quad (74)$$

where $A_4 = \sqrt{(24\sqrt{3})^2 + (4\sqrt{6}(1 + \pi))^2 + (6\sqrt{6})^2} = 2\sqrt{6(85 + 8\pi + 4\pi^2)} \approx 59.93$. \square

4.3. \mathbb{W}^1 -error estimate when taking into account pairwise interactions. When the approximation $\varphi \approx \sum_{j=1}^N \varphi_{c_j}$ is not accurate enough, a more accurate approximate solution can be obtained by using the two terms expansion

$$\varphi = \sum_{j=1}^N \varphi_{c_j} + \sum_{j=1}^N \sum_{\substack{k=1 \\ k \neq j}}^N \psi_{c_k, c_j} + \chi \quad (75)$$

where χ denotes the approximation error.

Proposition 7. *The remainder χ in (75) satisfies*

$$\begin{cases} \Delta \chi = 0 & \text{in } \Omega_1, \dots, \Omega_N \text{ and } \Omega^c \\ \left[\mu \frac{\partial \chi}{\partial n} \right] = [\mu] g_1 & \text{across } \Sigma_1, \dots, \Sigma_N \end{cases} \quad (76)$$

where the data g_1 is defined by

$$\forall x \in \Sigma_i \quad g_1(x) = - \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{\substack{k=1 \\ k \neq j}}^N \nabla \psi_{c_k - c_j, 0}(T_{c_j}(x)) \cdot n(x).$$

Moreover, the source term g_1 satisfies

$$\|g_1\|_{\mathbb{L}^\infty} \leq A_4 \lambda_p \left(\frac{2\varepsilon}{\delta}\right)^5 \left(B_3 + 3 \ln\left(\frac{2}{\delta}\right)\right) \left(B_3 \text{Li}_{-\frac{3}{2}}\left(\frac{2\varepsilon}{\delta}\right) + 3\left(\frac{2\varepsilon}{\delta}\right) \ln\left(\frac{2}{\delta}\right)\right). \quad (77)$$

Proof. Since the functions φ , φ_{c_j} and ψ_{c_k, c_j} for $j, k \in \{1, \dots, N\}$, $k \neq j$, all satisfy the Laplace equation in each domain Ω_i , $i = 1, \dots, N$ and in Ω^c , it follows from (75) by linearity that χ also satisfies the Laplace equation. Moreover, for all $i \in \{1, \dots, N\}$ we have

$$\left[\mu \frac{\partial \chi}{\partial n} \right] = \left[\mu \frac{\partial \psi}{\partial n} \right] - \sum_{j=1}^N \sum_{\substack{k=1 \\ k \neq j}}^N \left[\mu \frac{\partial \psi_{c_k, c_j}}{\partial n} \right] \text{ across } \Sigma_i. \quad (78)$$

From (21), (22) and (45), we can express the interface condition (78) across Σ_i as

$$\left[\mu \frac{\partial \chi}{\partial n} \right] = \underbrace{[\mu] g_0 - \sum_{\substack{k=1 \\ k \neq i}}^N \left[\mu \frac{\partial \psi_{c_k, c_i}}{\partial n} \right]}_{=0} - \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{\substack{k=1 \\ k \neq j}}^N \left[\mu \frac{\partial \psi_{c_k, c_j}}{\partial n} \right]. \quad (79)$$

The potential ψ_{c_k, c_j} solution to problem (45) is continuous in \mathbb{R}^3 and has regularity \mathcal{C}^∞ everywhere except on the boundary Σ_j . Therefore, as soon as $|c_i - c_j| > 2\varepsilon$ (that corresponds to the fact that the particles Ω_i and Ω_j of radius ε do not intersect) the normal derivative $\frac{\partial \psi_{c_k, c_j}}{\partial n}$ is continuous across Σ_i and (79) reads

$$\left[\mu \frac{\partial \chi}{\partial n} \right] = -[\mu] \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{\substack{k=1 \\ k \neq j}}^N \frac{\partial \psi_{c_k, c_j}}{\partial n} = -[\mu] \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{\substack{k=1 \\ k \neq j}}^N (\nabla \psi_{c_k - c_j, 0} \circ T_{c_j}) \cdot n. \quad (80)$$

The first result stated in the lemma is proven. In order to obtain the estimate on the source term g_1 , we start with

$$\forall i \in \{1, \dots, N\} \quad \forall x \in \Sigma_i \quad |g_1(x)| \leq \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{\substack{k=1 \\ k \neq j}}^N |\nabla \psi_{\text{ref}}^{c_k - c_j}(x - c_j)|.$$

We deduce from Proposition 6 that

$$|g_1(x)| \leq A_4 \lambda_p \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{\substack{k=1 \\ k \neq j}}^N \frac{\varepsilon^5}{(|c_k - c_j| - \varepsilon)^3 |c_j - x|^2} \text{Li}_{-\frac{3}{2}}\left(\frac{\varepsilon}{|c_j - x|}\right).$$

From the definition of the Polylogarithm function and the inequality $|c_k - c_j| - \varepsilon \geq \frac{1}{2}|c_k - c_j|$, it follows that

$$|g_1(x)| \leq A_4 \lambda_p \sum_{\ell=1}^{+\infty} \ell^{\frac{3}{2}} \varepsilon^{\ell+2} \sum_{\substack{j=1 \\ j \neq i}}^N \frac{1}{|c_j - x|^{\ell+2}} \sum_{\substack{k=1 \\ k \neq j}}^N \frac{\varepsilon^3}{|c_k - c_j|^3}.$$

Using relation (90) of Appendix B, we can bound the last sum to obtain

$$|g_1(x)| \leq A_4 \lambda_p \left(\frac{2\varepsilon}{\delta}\right)^3 \left(B_3 + 3 \ln\left(\frac{2}{\delta}\right)\right) \sum_{\ell=1}^{+\infty} \ell^{\frac{3}{2}} \varepsilon^{\ell+2} \sum_{\substack{j=1 \\ j \neq i}}^N \frac{1}{|c_j - x|^{\ell+2}}.$$

Finally, using relations (90) and (91) of Appendix B, we can bound the sums $\sum_{\substack{j=1 \\ j \neq i}}^N \frac{1}{|c_j - x|^{\ell+2}}$ and for all $\ell \geq 1$ to conclude that

$$|g_1(x)| \leq A_4 \lambda_p \left(\frac{2\varepsilon}{\delta}\right)^5 \left(B_3 + 3 \ln\left(\frac{2}{\delta}\right)\right) \left(B_3 \text{Li}_{-\frac{3}{2}}\left(\frac{2\varepsilon}{\delta}\right) + 3 \left(\frac{2\varepsilon}{\delta}\right) \ln\left(\frac{2}{\delta}\right)\right).$$

□

Following the same steps as in the proof of Theorem 1, we deduce the following result.

Theorem 3. *Let $\Omega_1, \dots, \Omega_N$ be N isolated spherical particles in $B(0, 1) \subset \mathbb{R}^3$, centered respectively at c_j , $j \in \{1, \dots, N\}$ with the same radius ε . For all $j, k \in \{1, \dots, N\}$, $i \neq k$, let $\varphi_{c_j} \in \mathbb{W}_0^1(\mathbb{R}^3)$ be the solution to problem (19) and $\psi_{c_k, c_j} \in \mathbb{W}_0^1(\mathbb{R}^3)$ be the solution to problem (45). We have*

$$\begin{aligned} \left\| \varphi - \left(\sum_{j=1}^N \varphi_{c_j} + \sum_{j=1}^N \sum_{\substack{k=1 \\ k \neq j}}^N \psi_{c_k, c_j} \right) \right\|_{\mathbb{W}^1(\mathbb{R}^3)} &\leq A_1 A_4 (\mu_p - 1) \lambda_p N \varepsilon^{\frac{3}{2}} \left(\frac{2\varepsilon}{\delta}\right)^5 \left(B_3 + 3 \ln\left(\frac{2}{\delta}\right)\right) \\ &\quad \times \left(B_3 \text{Li}_{-\frac{3}{2}}\left(\frac{2\varepsilon}{\delta}\right) + 3 \left(\frac{2\varepsilon}{\delta}\right) \ln\left(\frac{2}{\delta}\right) \right) \end{aligned} \quad (81)$$

where δ is the minimal distance between two particles as defined in (1). Note that all the constants have been explicitly estimated and are summarized in table 2 on p. 36.

Remark 4. When $\frac{2\varepsilon}{\delta}$ becomes small, since $\text{Li}_{-\frac{3}{2}}(z) \sim_0 z$, estimate (81) reads

$$\left\| \varphi - \left(\sum_{j=1}^N \varphi_{c_j} + \sum_{j=1}^N \sum_{\substack{k=1 \\ k \neq j}}^N \psi_{c_k, c_j} \right) \right\|_{\mathbb{W}^1(\mathbb{R}^3)} \lesssim (\mu_p - 1) \lambda_p N \varepsilon^{\frac{3}{2}} \left(\frac{2\varepsilon}{\delta}\right)^6 \left(1 + \ln\left(\frac{2}{\delta}\right)\right)^2$$

and this new bound is the product of a term $N \varepsilon^{\frac{3}{2}}$ of the order of φ , and the square of the first order error $\left(\frac{2\varepsilon}{\delta}\right)^3 \left(1 + \ln\left(\frac{2}{\delta}\right)\right)$.

5. NUMERICAL INVESTIGATIONS

Based on the mathematical investigations conducted in the previous sections, we have developed a computer program under MATLAB to compute the magnetic potential φ solution to problem (6). The computer program offers the possibility to compute the magnetic potential with either one term or two terms in the series expansion corresponding respectively to the results stated in theorem 1 and theorem 3. Computation of the first term in the expansion given by $\sum_{j=1}^N \varphi_{c_j}$ is straightforward since $\varphi_{c_j} = \varphi_{\text{ref}} \circ T_{c_j}$ and the expression of φ_{ref} is given by (15). Computation of the second term $\sum_{j=1}^N \sum_{\substack{k=1 \\ k \neq j}}^N \psi_{c_k, c_j}$, where $\psi_{c_k, c_j} = \psi_{\text{ref}}^{c_k - c_j} \circ T_{c_j}$, that takes into account pairwise interaction relies on the series expansion given by Lemma 2. Namely, for all $x = (r, \theta, \eta) \in \mathbb{R}^3$

$$\psi_{\text{ref}}^{c_k - c_j}(r, \theta, \eta) = \begin{cases} \sum_{\ell=1}^{+\infty} \left(\frac{r}{\varepsilon}\right)^\ell \sum_{m=-\ell}^{\ell} \gamma_\ell^m Y_\ell^m(\theta, \eta) & \text{if } |x - c_j| \leq \varepsilon \\ \sum_{\ell=1}^{+\infty} \left(\frac{\varepsilon}{r}\right)^{\ell+1} \sum_{m=-\ell}^{\ell} \gamma_\ell^m Y_\ell^m(\theta, \eta) & \text{if } |x - c_j| > \varepsilon \end{cases} \quad (82)$$

where we have set

$$\gamma_\ell^m = \frac{(\mu_p - 1)\varepsilon}{(\mu_p + 1)\ell + 1} \int_0^{2\pi} \left(\int_0^\pi g(\theta, \eta) \overline{Y_\ell^m}(\theta, \eta) \sin(\theta) \, d\theta \right) \, d\eta. \quad (83)$$

Of course, in a numerical approach, the series expansions (82) have to be truncated to an integer L and the efficiency of the method depends on the convergence to zero of the series coefficients γ_ℓ^m as ℓ increases to infinity.

5.1. Convergence toward zero of the series coefficients. In order to illustrate the fast convergence to 0 of the coefficients γ_ℓ^m given by (83) as ℓ tends to infinity, we have depicted in Fig. 4 the values $|g_\ell^m|$ for $m = -\ell, \dots, \ell$ and $\ell = 0, \dots, 15$ for $\mu_p = 10$, $\varepsilon = 1$ and $u = c_k - c_j = (1, 1, 1)^\top$. We have also depicted in Fig. 5 the decimal logarithm of $\max_{m=-\ell, \dots, \ell} |g_\ell^m|$ for $\ell = 1, \dots, 29$. The slope of the straight line is approximately -0.2 . This means that from ℓ to $\ell + 1$ the maximal value $\max_{m=-\ell, \dots, \ell} |g_\ell^m|$ is divided by 1.6.

5.2. Illustration of the mathematical results. We start with an illustration of the behavior of the bound in the estimate provided in theorem 2. We consider two spherical particles ($N = 2$) with radius $\varepsilon = 1$ mm aligned in the e_1 direction. For two particles, we have

$$\mathfrak{E} := \max_{x \in \mathbb{R}^3} \left| \varphi(x) - \sum_{j=1}^2 \varphi_{c_j}(x) \right| = \max_{x \in \mathbb{R}^3} \left| \sum_{j=1}^2 \sum_{\substack{k=1 \\ k \neq j}}^2 \psi_{c_k, c_j} \right| \quad (84)$$

since with two particles, there is nothing else than pairwise interactions. We have computed \mathfrak{E} considering two particles at various distance δ from each other for $\mu_p = 10$ and $H_0 = \frac{1}{\mu_0} (1 \ 0 \ 0)^\top \text{ H.m}^{-1}$. We have depicted in Fig. 6 the quantity \mathfrak{E} as a function of the distance δ between the two spherical particles in log-scale. One can observe that \mathfrak{E} varies as $1/\delta^3$ as predicted by theorem 2.

We then consider two spherical particles ($N = 2$) with radius ε aligned in the e_1 direction with centers at a distance $\delta = 11$ mm. We have computed \mathfrak{E} considering various radius ε for $\mu_p = 10$ and $H_0 = \frac{1}{\mu_0} (1 \ 0 \ 0)^\top \text{ H.m}^{-1}$. We have depicted in Fig. 7 the quantity \mathfrak{E} as a function of the radius ε of the two spherical particles in log-scale. One can observe that \mathfrak{E} varies as ε^4 as predicted by theorem 2. By linear least-square interpolation, the vertical intercept is found to be 1.053865×10^3 . In the estimate provided in theorem 2, for $\delta = 1$, the first term in the series expansion in ε is $16 \frac{(\mu_p - 1)^2}{\mu_p + 2} (B_3 + 3 \ln 2) M_x \leq 2.8 \times 10^5$ since

FIGURE 4. Values of $|g_\ell^m|$ for $m = -\ell, \dots, \ell$ and $\ell = 0, \dots, 16$ for $\mu_p = 10$, $\varepsilon = 1$ and $u = c_k - c_j = (1, 1, 1)^\top$.

FIGURE 5. Values of the decimal logarithm of $\max_{m=-\ell, \dots, \ell} |g_\ell^m|$ for $\ell = 1, \dots, 29$ for $\mu_p = 10$, $\varepsilon = 1$ and $u = c_k - c_j = (1, 1, 1)^\top$.

$M_x \leq N = 2$. The bound provided in theorem 2 is therefore not a sharp bound in this particular case.

5.3. Numerical experiments. As a first numerical experiment, we consider the case of two spherical particles with magnetic permeability $\mu_p = 10$ and radius $\varepsilon = 1$ mm subjected to a magnetic field aligned with the ball centers with intensity $H_0 = \frac{1}{\mu_0} \text{H.m}^{-1}$. The two ball centers are separated by $\delta = 3$ mm, i.e. the two spheres are at a distance of one radius.

FIGURE 6. Values of \mathfrak{E} as a function of the distance δ between the two spherical particles in a log-scale. The slope of the solid line is -3 .

FIGURE 7. Values of \mathfrak{E} as a function of the radius ε of the two spherical particles in a log-scale. The slope of the solid line is 4 .

The plane of reference where the magnetic potential is computed is a plane passing through the ball centers with size 9ε along the y -axis and 4ε along the x -axis. We have depicted in Fig. 8 the potential $\varphi_{c_1} + \varphi_{c_2}$ corresponding to the first term in our series expansion, *i.e.* obtained by neglecting interaction between the balls, the potential $\psi_{c_1,c_2} + \psi_{c_2,c_1}$ corresponding to the second term in the series expansion, *i.e.* corresponding to the pairwise interactions between the two balls and the second order series approximation of the magnetic potential $\varphi \approx \varphi_{c_1} + \varphi_{c_2} + \psi_{c_1,c_2} + \psi_{c_2,c_1}$. These three quantities were computed over a grid of 50×100

points in the plane of reference. Computation time (CPU time) was 51.03 s under MATLAB (R2018a) on an Intel i5 Quad Core desktop computer.

In this first test case, one can see that the second term in the series expansion that takes into account pairwise interactions between the two balls amounts to around 7 % of the total magnetic potential.

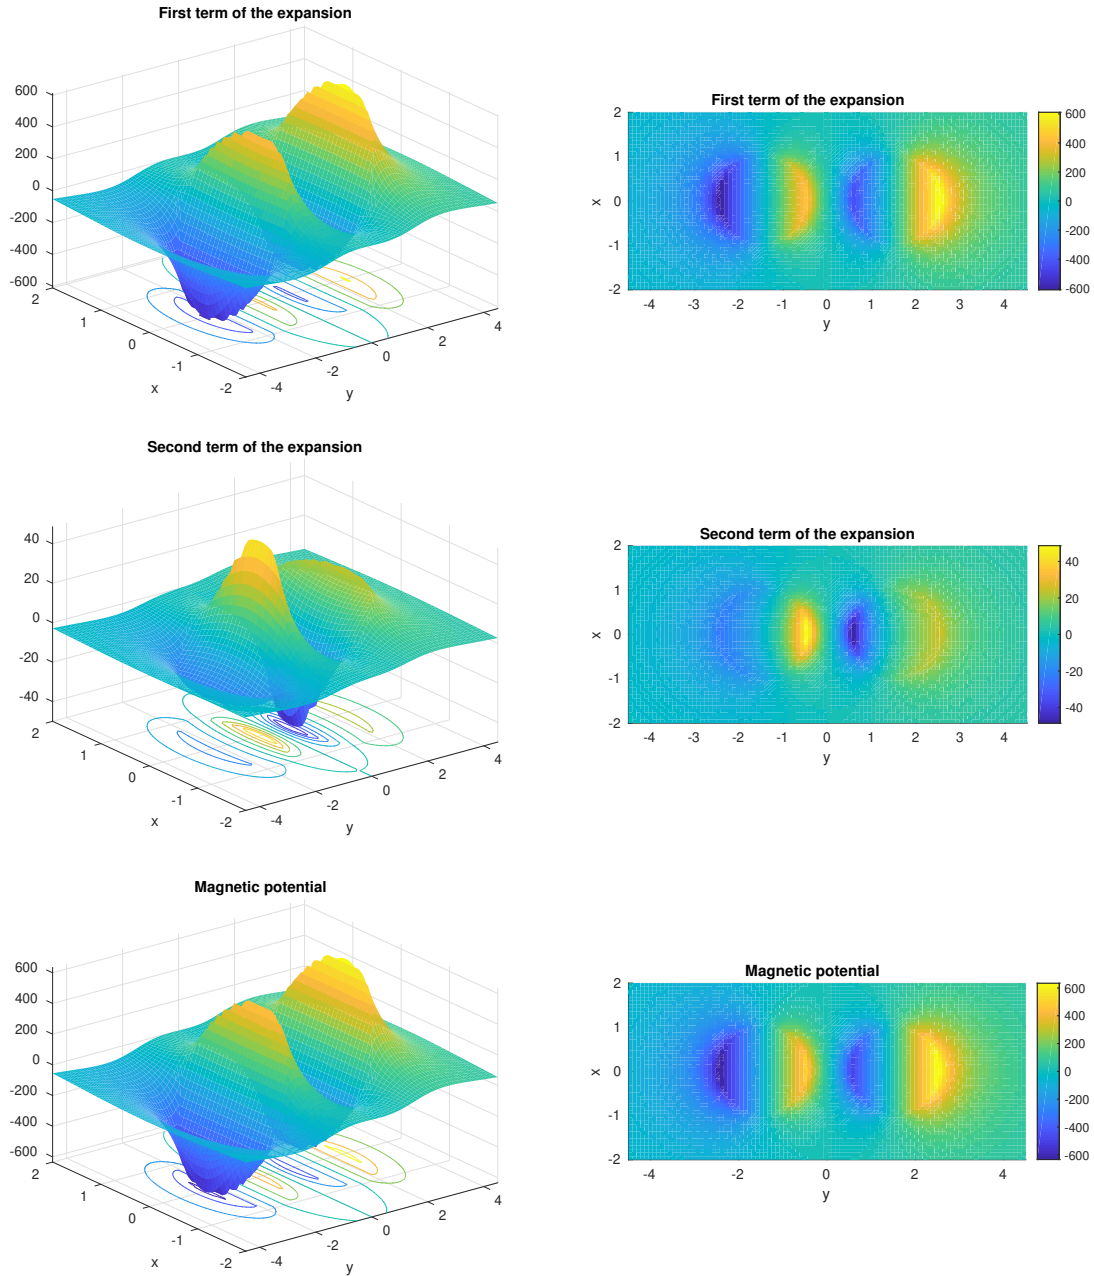

FIGURE 8. Two particles. From top to bottom : first term in the series expansion of the magnetic potential, second term in the series expansion and approximation of the magnetic potential obtained by summing the first two terms of the series expansion. From left to right : three-dimensional shaded surface representation and two-dimensional representation of the three quantities.

In order to validate our computer program based on the series expansion presented in the paper, we have also compared the second order series approximation of the magnetic

potential $\varphi \approx \varphi_{c_1} + \varphi_{c_2} + \psi_{c_1, c_2} + \psi_{c_2, c_1}$ to the magnetic potential φ computed by the Finite Element Method (FEM) using the free software FREEFEM++ [9]. Note that the solution provided by the FEM is to be considered as a reference solution. It is not the exact solution because of the discretization error (the magnetic potential is approached by Lagrange P_2 Finite Element on a fine triangulation mesh of the computational domain) and the need to bound the computational domain by introducing an artificial boundary and a (approximate) boundary condition that takes account of the behavior of the magnetic potential at infinity. The relative maximal error over the computational grid on the plane of reference between the FEM solution and the solution computed by the two terms series expansion was found to be 0.67% whereas the relative quadratic error was 0.63%. For the sake of completeness, we should add that comparing the FEM solution to the solution $\varphi_{c_1} + \varphi_{c_2}$ obtained under the non-interaction assumption we obtain a relative maximal error of 5.78% and a relative quadratic error of 5.18%. Thus, in this test example, we can conclude that taking into account pairwise interactions significantly improves the accuracy.

To go further in the numerical investigations, we have computed the relative maximal error and the relative quadratic error for various values of the parameter δ/ε when only one term in the potential series expansion is taken into account (this corresponds to the "non-interacting assumption" case) and when the first two terms are taken into account (this corresponds to the "pairwise interactions" case). One can see on the results given in Table 1 that when the two ball centers are at a distance lower than 5ε , the error made on the computation of the magnetic potential assuming that the particles have no magnetic interaction lead to a significant error. On the contrary, taking into account pairwise interactions provide good results with an error about one percent. One can also observe that when the particles become very close to each other, the error obtained with two terms in the potential series expansion tends to increase. In our test example, it is around 3% when the particles are at a distance of a quarter of their radius. This indicates that when the particles are very close to each other, one should compute a third term in the potential series expansion.

	δ/ε	2.25	2.5	3	4	5	6	7
1 term	Max. error (%)	16.34	11.08	5.78	1.95	0.77	0.62	0.65
	Quad. error (%)	14.62	9.76	5.18	1.75	0.73	0.47	0.61
2 terms	Max. error (%)	3.07	1.23	0.67	0.71	0.71	0.77	0.82
	Quad. error (%)	2.46	1.05	0.63	0.86	0.89	0.73	0.95

TABLE 1. Maximal Error and quadratic error obtained when using one and two terms in the magnetic potential series expansion as a function of $\frac{\delta}{\varepsilon}$, i.e. as a function of the distance between the two ball centers. Note that for $\frac{\delta}{\varepsilon} = 2$, the balls are touching each other.

As a second test example, we have considered a cube of $4^3 = 64$ balls with radius $\varepsilon = 1$ mm regularly spaced with a distance between their centers $\delta = 3$ mm. The balls are subjected to a magnetic field aligned with x -direction with intensity $H_0 = \frac{1}{\mu_0}$ H.m⁻¹. The plane of reference where the magnetic potential is computed is a plane passing through the center of the cube with basis vectors corresponding to the x and y directions. The magnetic potential is computed on 100^2 equidistant points on a square grid with size 15ε . Computations lasted 59 872 s. (approx. 16h30) to compute the $64 \times 63 = 4032$ particles pairwise interactions. In this test example, the second term of the series expansion is about 3.5% of the first term. To temper the important simulation time observed, several remarks can be made. The first one is that the main computational cost is the computation, for each pairwise interaction, of the series coefficients γ_ℓ^m defined in (83) for all $m = -\ell, \dots, \ell$ and for all $\ell = 1, \dots, L$ where L is the number of terms taken into account in the truncated series (we took $L = 16$). We

have used a basic quadrature approach to evaluate γ_ℓ^m but actually the spherical harmonics integrals involved in the definition (83) of γ_ℓ^m could be computed by fast spherical Fourier algorithms [15]. We can add that for the sake of graphical representation, the magnetic potential was computed on a bi-dimensional grid but computation on a three-dimensional grid would not significantly increase the overall computation time. The second remark is that simulation was achieved on a desktop computer, not on a server dedicated to scientific computing. In such a computer, computation time could be drastically reduced by parallel programming. Indeed, each particle pairwise interaction can be computed independently from each other.

6. CONCLUSION

In the first part of the paper, we have investigated the validity of the approach consisting in neglecting magnetic interactions between particles in the numerical computation of the magnetic field inhomogeneities induced by a cluster of metallic particles subjected to a uniform magnetic field. Such a situation is encountered in various contexts in Magnetic Resonance Imaging. We have obtained bounds for the approximation error in terms of the three geometrical key parameters that were found to be the number of particles N , the radius ε of the particles (assumed to have a spherical shape for simplicity), and the distance δ between the two nearest particles. Two other physical parameters, the magnetic permeability μ_p of the particles and the strength of the inductive magnetic field H_0 are also involved in the error bound. The main conclusion of the analysis carried out on the "non-interacting assumption" is that the error is proportional to ε^4/δ^3 . This behavior has also been observed in numerical experiments presented in the paper.

When the "non-interacting assumption" is deficient, we have proposed in the second part of the paper a method to compute a better approximation of the magnetic potential by taking into account pairwise magnetic field interactions between particles that enters in a general framework for computing the scalar magnetic potential as a series expansion. Numerical computation of pairwise magnetic field interactions relies on the evaluation of spherical harmonics series. Each pairwise interaction between two particles requires the evaluation of a spherical harmonics series. Fortunately, the series coefficients tend very quickly toward zero and in practise only a dozen of coefficients need to be evaluated. Moreover, computation of the series coefficient relies on the evaluation of spherical harmonics integrals for which fast spherical Fourier algorithms are available [15]. And lastly, the method has good parallelisation properties which suggests that an efficient simulation software could be developed to deal with e.g. the applications in MRI quoted in the introduction. We have also obtained error bounds in terms of the above mentioned key parameters for the approximation of the magnetic potential taking into account pairwise interactions.

APPENDICES

APPENDIX A. TRACE AND INJECTION

It's well known (see [5, page 119]) that functions belonging to $\mathbb{W}_0^1(\mathbb{R}^3)$ admit a trace on the surfaces Σ_j , $j \in \{1, \dots, N\}$, and that the trace defines a continuous mapping from $\mathbb{W}_0^1(\mathbb{R}^3)$ onto $\mathbb{H}^{\frac{1}{2}}(\Sigma_j)$. From Sobolev's embedding results, we also deduce that $\mathbb{W}_0^1(\mathbb{R}^3)$ is continuously

injected in $\mathbb{L}^1(\Sigma_j)$:

$$\forall j \in \{1, \dots, N\} \quad \exists C_j > 0 \quad \forall \varphi \in \mathbb{W}_0^1(\mathbb{R}^3) \quad \|\varphi\|_{\mathbb{L}^1(\Sigma_j)} \leq C_j \|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)}.$$

The following proposition provides the constants C_j when the surfaces Σ_j are balls with radius ε .

Proposition 8. *For all $j \in \{1, \dots, N\}$ and for all $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ we have*

$$\|\varphi\|_{\mathbb{L}^1(\Sigma_j)} \leq A_1 \varepsilon^{\frac{3}{2}} \|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)}, \quad (85)$$

where $A_1 = \sqrt{4\pi}$.

Proof. We first consider the case where Σ_j is the unit sphere S^2 centered at the origin and with radius 1. By a density argument, we can consider functions ψ in $\mathcal{C}_0^\infty(\mathbb{R}^3)$. In the spherical coordinates system (r, θ, η) , we have

$$\begin{aligned} \int_{S^2} |\psi(1, \theta, \eta)| \sin \theta \, d\theta d\eta &\leq \int_1^\infty \int_{S^2} |\partial_r \psi(r, \theta, \eta)| \sin \theta \, d\theta d\eta dr \\ &\leq \sqrt{\int_1^\infty \int_{S^2} \frac{1}{r^2} \sin \theta \, d\theta d\eta dr} \sqrt{\int_1^\infty \int_{S^2} |\partial_r \psi(r, \theta, \eta)|^2 r^2 \sin \theta \, d\theta d\eta dr}. \end{aligned}$$

It follows that

$$\|\psi\|_{\mathbb{L}^1(S)} \leq \sqrt{4\pi} \|\psi\|_{\mathbb{W}^1(\mathbb{R}^3)}. \quad (86)$$

In the case where Σ_j is a sphere centered in c_j and with radius $\varepsilon > 0$, we use the change of variable $y \in S^2 \mapsto x = c_j + \varepsilon y \in \Sigma_j$. More precisely, for $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ we define ψ such that $\psi(y) = \varphi(x)$. We have

$$\|\varphi\|_{\mathbb{L}^1(\Sigma_j)} = \varepsilon^2 \|\psi\|_{\mathbb{L}^1(S)} \quad \text{and} \quad \|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)} = \sqrt{\varepsilon} \|\psi\|_{\mathbb{W}^1(\mathbb{R}^3)}. \quad (87)$$

The estimate (86) together with (87) directly implies (85). \square

The Sobolev injection indicates that $\mathbb{H}^{\frac{1}{2}}(\Sigma_j) \subset \mathbb{L}^4(\Sigma_j)$ and we also have the following finer result.

Proposition 9. *For all $j \in \{1, \dots, N\}$ and for all $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ we have*

$$\|\varphi\|_{\mathbb{L}^4(\Sigma_j)} \leq A_2 \|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)}, \quad (88)$$

where $A_2 = \frac{2}{3^{\frac{3}{8}} \sqrt{\pi}}$.

Proof. As in the proof of Proposition 8, we only have to deal with the case where Σ_j is the unit sphere S^2 . We also assume that φ belongs to $\mathcal{C}_0^\infty(\mathbb{R}^3)$ since the estimate for $\varphi \in \mathbb{W}_0^1(\mathbb{R}^3)$ will follow by density. Using the spherical coordinates (r, θ, η) , we have

$$\begin{aligned} \|\varphi\|_{\mathbb{L}^4(S^2)}^4 &= \int_{S^2} |\varphi(1, \theta, \eta)|^4 \sin \theta \, d\theta d\eta \leq 4 \int_1^\infty \int_{S^2} |\varphi(r, \theta, \eta)|^3 |\partial_r \varphi(r, \theta, \eta)| \sin \theta \, d\theta d\eta dr \\ &\leq 4 \sqrt{\int_1^\infty \int_{S^2} |\varphi(r, \theta, \eta)|^6 \sin \theta \, d\theta d\eta dr} \sqrt{\int_1^\infty \int_{S^2} |\partial_r \varphi(r, \theta, \eta)|^2 \sin \theta \, d\theta d\eta dr} \\ &\leq 4 \|\varphi\|_{\mathbb{L}^6(\mathbb{R}^3)}^3 \|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)}. \end{aligned}$$

Using the following Sobolev embedding result in \mathbb{R}^3 , see [7, page 26],

$$\|\varphi\|_{\mathbb{L}^6(\mathbb{R}^3)}^3 \leq \left(\frac{4}{3}\right)^{\frac{3}{2}} \frac{1}{2\pi^2} \|\nabla \varphi\|_{\mathbb{L}^2(\mathbb{R}^3)}^3. \quad (89)$$

we deduce that

$$\|\varphi\|_{\mathbb{L}^4(S^2)} \leq \frac{2}{3^{\frac{3}{8}} \sqrt{\pi}} \|\varphi\|_{\mathbb{W}^1(\mathbb{R}^3)}.$$

\square

APPENDIX B. SOME RESULTS ON THE SUM OF POWERS OF THE INVERSE DISTANCE

The results given in the following proposition are used in the study of the behavior of the various terms in the expansion of the magnetic potential.

Proposition 10. *Let $\Omega_1, \dots, \Omega_N$ be N spherical particles in $B(0, 1) \subset \mathbb{R}^3$, centered respectively at c_j , $j \in \{1, \dots, N\}$, with the same radius $\varepsilon > 0$. Let δ be the minimal distance between two particles as defined in (1).*

For all $i \in \{1, \dots, N\}$ and for all $x \in \mathbb{R}^3$ such that $\text{dist}(x, \Sigma_i) \leq \frac{\delta}{2}$, we have

$$\sum_{\substack{j=1 \\ j \neq i}}^N \frac{1}{|c_j - x|^3} \leq \left(B_3 + 3 \ln \left(\frac{2}{\delta} \right) \right) \left(\frac{2}{\delta} \right)^3, \quad (90)$$

where $B_3 = 142 + 3 \ln 2 \approx 144.1$. Moreover, for all $p \geq 4$, we have

$$\sum_{\substack{j=1 \\ j \neq i}}^N \frac{1}{|c_j - x|^p} \leq 137 \left(\frac{2}{\delta} \right)^p. \quad (91)$$

Proof. Let $i \in \{1, \dots, N\}$, $x \in \mathbb{R}^3$ such that $\text{dist}(x, \Sigma_i) \leq \frac{\delta}{2}$. For $p \geq 1$, we split the sum

$$S_i^{(p)}(x) = \sum_{\substack{j=1 \\ j \neq i}}^N \frac{1}{|c_j - x|^p}$$

into two parts. The first one concerns the indices j such that the particles Ω_j with center c_j are at a distance lower than 2δ from Ω_i . The second one concerns the indices j such that the particles Ω_j are not in this neighborhood. Moreover, since the volume of the ball $B(c_j, \frac{\delta}{2})$ is $\frac{\pi}{6} \delta^3$, we have

$$S_i^{(p)}(x) = \sum_{\substack{j=1, j \neq i \\ |c_j - c_i| < 2\delta}}^N \frac{1}{|c_j - x|^p} + \sum_{\substack{j=1, j \neq i \\ |c_j - c_i| \geq 2\delta}}^N \frac{6}{\pi \delta^3} \int_{B(c_j, \frac{\delta}{2})} \frac{dy}{|c_j - x|^p}. \quad (92)$$

The number of terms in the first sum in the RHS of (92), denoted $S_{i,1}^{(p)}$ in the sequel, is bounded independently of N . Actually, this number is lower than the cardinal number C of the set of points in $B(0, 2) \setminus B(0, 1)$, such that the pairwise distance is larger than 1. By volume considerations, this number is found to be less than the quotient obtained by dividing the volume of $B(0, \frac{5}{2}) \setminus B(0, \frac{1}{2})$ by the volume of $B(0, \frac{1}{2})$ that is to say 124. Each term in $S_{i,1}$ is smaller than $\frac{1}{(\delta/2)^p}$ so that

$$S_{i,1}^{(p)} \leq 124 \left(\frac{2}{\delta} \right)^p. \quad (93)$$

Let us now obtain an estimate of the second sum in the RHS of (92), denoted $S_{i,2}^{(p)}$ in the sequel. First of all, from the triangular inequality, we note that for all $y \in B(c_j, \frac{\delta}{2})$,

$$|y - c_i| \leq |y - c_j| + |c_j - x| + |x - c_i| \leq \frac{\delta}{2} + |x - c_j| + \frac{\delta}{2} = |x - c_j| + \delta.$$

It follows that $|x - c_j| \geq |y - c_i| - \delta$ and

$$\begin{aligned} S_{i,2}^{(p)} &\leq \frac{6}{\pi \delta^3} \sum_{\substack{j=1, j \neq i \\ |c_j - c_i| \geq 2\delta}}^N \int_{B(c_j, \frac{\delta}{2})} \frac{dy}{(|y - c_i| - \delta)^p} \\ &\leq \frac{6}{\pi \delta^3} \int_{B(c_i, 2) \setminus B(c_i, \frac{3}{2}\delta)} \frac{dy}{(|y - c_i| - \delta)^p} \end{aligned} \quad (94)$$

since under our assumptions for all $j = 1, \dots, N$, $j \neq i$, we have $B(c_j, \frac{\delta}{2}) \subset B(c_i, 2) \setminus B(c_i, \frac{3}{2}\delta)$. The last integral in (94) can be expressed in spherical coordinates, and then it can be explicitly evaluated. We obtain

$$S_{i,2}^{(p)} \leq \frac{24}{\delta^3} \int_{\frac{3}{2}\delta}^2 \frac{r^2 dr}{(r-\delta)^p} = \frac{24}{\delta^3} \int_{\frac{\delta}{2}}^{2-\delta} \frac{(s+\delta)^2}{s^p} ds := \frac{24}{\delta^3} I_p.$$

We now distinguish the different possible values of p envisaged in the proposition since the integral takes different closed form expressions depending on the value of p .

- Case $p = 3$. We have

$$I_3 = \int_{\frac{\delta}{2}}^{2-\delta} \frac{(s+\delta)^2}{s^3} ds = \frac{48 - 56\delta + 15\delta^2}{2(2-\delta)^2} + \ln\left(\frac{2}{\delta}(2-\delta)\right).$$

From (92) and (93), we deduce that

$$S_i^{(3)} \leq (3I_3 + 124) \left(\frac{2}{\delta}\right)^3.$$

One can show that the mapping $\delta \mapsto I_2$ is bounded by $18 + \ln 2 + \ln\left(\frac{2}{\delta}\right)$. This concludes the proof of estimate (90).

- Case $p \geq 4$. We have

$$I_p = \int_{\frac{\delta}{2}}^{2-\delta} \frac{(s+\delta)^2}{s^p} ds = \left[\frac{s^{3-p}}{3-p} + \frac{2\delta s^{2-p}}{2-p} + \frac{\delta^2 s^{1-p}}{1-p} \right]_{\frac{\delta}{2}}^{2-\delta} \leq \frac{13}{3} \left(\frac{2}{\delta}\right)^{p-3}.$$

We deduce that

$$S_{i,2}^{(p)} \leq 13 \left(\frac{2}{\delta}\right)^p.$$

From (92) and (93), we deduce the estimate (91). □

One of the important features of the estimates given in proposition (10) is that they are optimal. More precisely, the behaviour of the sums with respect to the variable δ is correctly estimated. This remark can be understood by looking at the case of a large number of particles ($N \rightarrow +\infty$) uniformly distributed in the ball $B(0, 1)$, with one particle located at the origin. To illustrate the situation, we consider the case $p = 3$. Let us assume that $c_1 = (0, 0, 0)$ for simplicity. Since δ measures the distance between the centers of two "adjacent" particles, these centers have for coordinates $(k_1\delta, k_2\delta, k_3\delta)$ where $(k_1, k_2, k_3) \in \mathbb{Z}^3$ with $\delta^2(k_1^2 + k_2^2 + k_3^2) \leq 1$. It is clear that the "worst" case, i.e. the one that makes the largest sum $S_i^{(3)}$, is the case $i = 1$. Thus, let us consider $S_1^{(3)}(0)$. For all $j \in \{2, \dots, N\}$, we have

$$S_1^{(3)}(0) = \sum_{\substack{j=1 \\ j \neq 1}}^N \frac{1}{|c_j|^3} = \sum_{\substack{(k_1, k_2, k_3) \in \mathbb{Z}^3 \\ 1 \leq k_1^2 + k_2^2 + k_3^2 \leq \frac{1}{\delta^2}}} \frac{1}{(\delta \sqrt{k_1^2 + k_2^2 + k_3^2})^3} = \frac{1}{\delta^3} \sum_{\substack{(k_1, k_2, k_3) \in \mathbb{Z}^3 \\ 1 \leq k_1^2 + k_2^2 + k_3^2 \leq \frac{1}{\delta^2}}} \frac{1}{(k_1^2 + k_2^2 + k_3^2)^{\frac{3}{2}}}.$$

When N is large, the last sum is the approximation by the mid-ordinate quadrature rule of the integral

$$I = \frac{1}{\delta^3} \int_{B(0, \frac{1}{\delta}) \setminus B(0,1)} \frac{dx}{(x_1^2 + x_2^2 + x_3^2)^{\frac{3}{2}}}.$$

This integral can be easily evaluated using spherical coordinates and we obtain

$$I = \frac{4\pi}{\delta^3} \int_1^{\frac{1}{\delta}} \frac{dr}{r} = \frac{4\pi}{\delta^3} \ln\left(\frac{1}{\delta}\right). \quad (95)$$

FIGURE 10. Notation for the spherical coordinates.

This shows that the estimate given in proposition 10 in the case $p = 3$ is optimal in the following sense: for $\delta = o(1)$ (that precisely corresponds to the case of many particles uniformly distributed in the ball $B(0, 1)$), estimate (90) reads

$$S_1^{(3)}(0) \leq \frac{a}{\delta^3} \ln\left(\frac{1}{\delta}\right),$$

the constant a being independent of N , δ and ε , whereas in the present example, using (95), we have

$$S_1^{(3)}(0) \geq \frac{b}{\delta^3} \ln\left(\frac{1}{\delta}\right),$$

where b is another constant independent of N , δ and ε .

APPENDIX C. EXPLICIT SOLUTION TO THE REFERENCE PROBLEM FOR THE FIRST TERM OF THE EXPANSION

In this appendix, we detail the way the explicit expression of the solution $\varphi_{\text{ref}} \in \mathbb{W}_0^1(\mathbb{R}^3)$ to problem (14) is obtained.

C.1. Variable separation method. In spherical coordinates, the Laplace equation is separable. We are looking for a solution φ_{ref} to problem (14) in the form

$$\varphi_{\text{ref}}(r, \theta, \eta) = u(r) \times v(\theta) \times w(\eta) \quad (96)$$

where u , v and w denote three complex valued functions of the real variable. The angles η and θ are the azimuthal angle and the polar angle respectively, see Fig. 10.

In spherical coordinates, the Laplace operator reads

$$\Delta \varphi_{\text{ref}} = \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \varphi_{\text{ref}} \right) + \frac{1}{r^2} \left(\frac{1}{\sin(\theta)} \frac{\partial}{\partial \theta} \left(\sin(\theta) \frac{\partial}{\partial \theta} \varphi_{\text{ref}} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \eta^2} \varphi_{\text{ref}} \right). \quad (97)$$

The Laplace equation $\Delta \varphi_{\text{ref}} = 0$ lends itself to being separated into a system of three ordinary differential equations: upon substituting ansatz (96) in the Laplace equation, one finds that for all $r \in \mathbb{R}_+^*$, $\theta \in]0, \pi[$ and $\eta \in]0, 2\pi[$,

$$\frac{1}{u(r)} \frac{d}{dr} \left(r^2 u'(r) \right) = \frac{1}{\sin^2(\theta)} \left(\frac{1}{v(\theta)} \sin(\theta) \frac{d}{d\theta} \left(\sin(\theta) v'(\theta) \right) + \frac{w'(\eta)}{w(\eta)} \right). \quad (98)$$

The left hand side of the equation depends only on the variable r whereas the right hand side depends only on the angular variables θ, η . It follows that the two terms are constant and

equal to the same constant p^2 , where p denotes a complex number. Thus, from the left hand side of (98), we deduce that for all $r \in \mathbb{R}_+^*$

$$\frac{1}{u(r)} \frac{d}{dr} (r^2 u'(r)) = p^2$$

and, from the right hand side of (98), we deduce that for all $\theta \in]0, \pi[$ and $\eta \in]0, 2\pi[$,

$$\frac{1}{v(\theta)} \sin(\theta) \frac{d}{d\theta} (\sin(\theta) v'(\theta)) - p^2 \sin^2(\theta) = \frac{w'(\eta)}{w(\eta)}.$$

Once again, the left hand side of the equation depends only on the polar variable θ whereas the right hand side depends only on the azimuthal variables η . It follows that the two terms are constant and equal to the same constant q^2 , where q denotes a complex number.

Finally, we conclude that the three unknown functions u , v and w satisfy for all $r \in \mathbb{R}_+^*$, $\theta \in]0, \pi[$ and $\eta \in]0, 2\pi[$,

$$r^2 u''(r) + 2r u'(r) - p^2 u(r) = 0 \quad (99a)$$

$$\frac{1}{\sin(\theta)} \frac{d}{d\theta} (\sin(\theta) v'(\theta)) + \left(p^2 - \frac{q^2}{\sin^2(\theta)}\right) v(\theta) = 0 \quad (99b)$$

$$w''(\eta) + q^2 w(\eta) = 0 \quad (99c)$$

where the real parameters p and q are the separation constants.

C.2. Angular dependency. Since the geometrical and physical properties of the ball are assumed to be independent of the azimuthal angle η , it is necessary for w to be a periodic function with period 2π . Then, the solution to equation (99c) reads

$$w(\eta) = C_1 e^{im\eta} + C_2 e^{-im\eta} \quad (100)$$

where the separation constant q coincides with an integer $m \in \mathbb{Z}$ and C_1 and C_2 denote two complex constants.

The change of variable $\tau = \cos(\theta)$ in equation (99b) leads to the equation

$$(1 - \tau^2) \widehat{v}''(\tau) - 2\tau \widehat{v}'(\tau) + \left(p^2 - \frac{m^2}{1 - \tau^2}\right) \widehat{v}(\tau) = 0 \quad (101)$$

where the new unknown function \widehat{v} is defined by the relations $v(\theta) = \widehat{v}(\cos(\theta))$. This equation is referred in the literature as the *general Legendre equation*. The solutions to the linear second order ordinary differential equation (ODE) (101) are the so-called *hypergeometric functions*, see [1] chp. 15. This equation has non-zero solutions that are nonsingular at ± 1 if and only if $p^2 = \ell(\ell + 1)$ with ℓ being a non negative integer such that $|m| \leq \ell$. In such a case, the solutions to equation (101) are the *associated Legendre functions*, see [21, 1], defined for $m \geq 0$ by

$$\widehat{v}(\tau) = P_\ell^m(\tau) := (-1)^m (1 - \tau^2)^{\frac{m}{2}} \frac{d^m}{d\tau^m} P_\ell(\tau) \quad (102)$$

where P_ℓ denotes the *Legendre polynomial* of degree ℓ defined for all $x \in]-1, 1[$ by

$$P_\ell(x) = \frac{1}{2^\ell \ell!} \frac{d^\ell}{dx^\ell} \left((x^2 - 1)^\ell \right).$$

The associated Legendre functions are sometimes defined without the multiplicative constant $(-1)^m$ which is known as the *Cordon-Shortley phase factor*. Following the standard convention, we set for negative values of the order

$$P_\ell^{-m}(x) = (-1)^m \frac{(\ell - m)!}{(\ell + m)!} P_\ell^m(x) \quad \forall x \in]-1, 1[.$$

For a fixed integer m , the associated Legendre functions satisfy the following orthogonality conditions for all $k, \ell \in \mathbb{N}$ such that $0 \leq m < \ell$

$$\int_{-1}^1 P_k^m P_\ell^m dx = 0$$

and

$$\int_{-1}^1 P_\ell^m P_\ell^m dx = \frac{2(\ell+m)!}{(2\ell+1)(\ell-m)!}.$$

Finally, we find the functions product $v(\theta) w(\eta)$ in the form of

$$Y_\ell^m(\theta, \eta) = C_{\ell m} P_\ell^m(\cos(\theta)) e^{im\eta} \quad -\ell \leq m \leq \ell, \quad \ell \in \mathbb{N} \quad (103)$$

where Y_ℓ^m is known as the *Spherical Surface Harmonics* of degree ℓ and order m , see [21]. The normalization constant $C_{\ell m}$ is taken to be

$$C_{\ell m} = \sqrt{\frac{(2\ell+1)(\ell-m)!}{4\pi(\ell+m)!}}. \quad (104)$$

With this normalization convention, the complex conjugate of the Spherical Surface Harmonics of degree ℓ and order m is

$$\overline{Y_\ell^m(\theta, \eta)} = (-1)^m Y_\ell^{-m}(\theta, \eta).$$

The Spherical Surface Harmonics form a complete set of orthonormal functions and thus they form an orthonormal basis of the Hilbert space of square-integrable functions on the unit sphere [21]. Namely, on the unit sphere any square-integrable function can be expanded as a linear combination of Spherical Surface Harmonics as:

$$h(\theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} h_\ell^m Y_\ell^m(\theta, \eta) \quad (105)$$

where the equality holds in $\mathbb{L}^2([0, \pi] \times [0, 2\pi], \mathbb{C})$ and

$$h_\ell^m = \int_0^{2\pi} \left(\int_0^\pi h(\theta, \eta) \overline{Y_\ell^m(\theta, \eta)} \sin(\theta) d\theta \right) d\eta.$$

C.3. Radial dependency. It remains to achieve the identification of the radial function u . It satisfies the following Euler differential equation deduced from (99a)

$$r^2 u''(r) + 2r u'(r) - \ell(\ell+1)u(r) = 0. \quad (106)$$

Two linearly independent solutions to the linear second order ordinary differential equation (106) are $r \mapsto r^\ell$ and $r \mapsto r^{-\ell-1}$. We deduce that the radial function u can be expressed as

$$u(r) = \alpha_\ell r^\ell + \beta_\ell \frac{1}{r^{\ell+1}}$$

where α_ℓ and β_ℓ denote two complex constant numbers.

We conclude that the general solution of the Laplace equation in spherical coordinates reads

$$\varphi_{\text{ref}}(r, \theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \left(\alpha_\ell^m r^\ell + \beta_\ell^m \frac{1}{r^{\ell+1}} \right) Y_\ell^m(\theta, \eta) \quad (107)$$

where α_ℓ^m and β_ℓ^m are complex numbers.

C.4. Boundary condition. Since φ_{ref} must be bounded for $r = 0$, the solution to problem (14) in $B(0, \varepsilon)$ reads

$$\varphi_{\text{ref}}(r, \theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \alpha_\ell^m r^\ell Y_\ell^m(\theta, \eta). \quad (108)$$

Moreover, since the magnetic potential must tend to zero at infinity, the solution in $\mathbb{C}B(0, \varepsilon)$ reads

$$\varphi_{\text{ref}}(r, \theta, \eta) = \sum_{\ell=0}^{+\infty} \sum_{m=-\ell}^{\ell} \beta_\ell^m \frac{1}{r^{\ell+1}} Y_\ell^m(\theta, \eta). \quad (109)$$

The constants α_ℓ^m and β_ℓ^m are determined by the following two conditions across $S(0, \varepsilon)$ in (14)

$$[\varphi_{\text{ref}}] = 0, \quad \left[\mu \frac{\partial \varphi_{\text{ref}}}{\partial n} \right] = [\mu] h. \quad (110)$$

In the situation considered here, the source term h depends only on the polar angle θ . This implies that the solution φ_{ref} will not depend on the azimuthal angle η and reads

$$\varphi_{\text{ref}}(r, \theta, \eta) = \varphi_{\text{ref}}(r, \theta) = \begin{cases} \sum_{\ell=0}^{+\infty} \alpha_\ell^0 r^\ell P_\ell^0(\theta) & \text{in } B(0, \varepsilon) \\ \sum_{\ell=0}^{+\infty} \beta_\ell^0 \frac{1}{r^{\ell+1}} P_\ell^0(\theta) & \text{in } \overline{\mathbb{C}B(0, \varepsilon)} \end{cases} \quad (111)$$

The interface conditions (110) give rise to the following linear system satisfied by the unknown coefficients α_ℓ^0 and β_ℓ^0 , $\ell \in \mathbb{N}$

$$\begin{aligned} \alpha_\ell^0 \varepsilon^\ell &= \beta_\ell^0 \frac{1}{\varepsilon^{\ell+1}} \quad \forall \ell \in \mathbb{N} \\ \beta_0^0 &= 0 \\ \mu_p \alpha_1^0 + 2\beta_1^0 \varepsilon^{-3} &= \mu_p - 1 \\ \ell \mu_p \alpha_\ell^0 + (\ell + 1) \beta_\ell^0 \varepsilon^{-\ell-2} &= 0 \quad \forall \ell \geq 2 \end{aligned}$$

Solving this linear system for α_ℓ^0 and β_ℓ^0 gives

$$\alpha_1^0 = \frac{\mu_p - 1}{\mu_p + 2}, \quad \beta_1^0 = \frac{\mu_p - 1}{\mu_p + 2} \varepsilon^3,$$

and $\alpha_\ell^0 = \beta_\ell^0 = 0$ for all $\ell \neq 1$. Finally, we conclude that

$$\varphi_{\text{ref}}(x) = \varphi_{\text{ref}}(r, \theta, \eta) = \begin{cases} \frac{\mu_p - 1}{\mu_p + 2} r \cos(\theta) = \frac{\mu_p - 1}{\mu_p + 2} e_3 \cdot x & \text{in } B(0, \varepsilon) \\ \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{r^2} \cos(\theta) = \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x|^3} e_3 \cdot x & \text{in } \overline{\mathbb{C}B(0, \varepsilon)} \end{cases} \quad (112)$$

The gradient of φ_{ref} is given in spherical coordinates by

$$\begin{aligned} \nabla \varphi_{\text{ref}}(r, \theta, \eta) &= \partial_r \varphi_{\text{ref}}(r, \theta, \eta) e_r + \frac{1}{r} \partial_\theta \varphi_{\text{ref}}(r, \theta, \eta) e_\theta + \frac{1}{r \sin(\theta)} \partial_\eta \varphi_{\text{ref}}(r, \theta, \eta) e_\eta \\ &= \begin{cases} \frac{\mu_p - 1}{\mu_p + 2} \left(\cos(\theta) e_r - \sin(\theta) e_\theta \right) & \text{in } B(0, \varepsilon) \\ \frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{r^3} \left(-2 \cos(\theta) e_r - \sin(\theta) e_\theta \right) & \text{in } \overline{\mathbb{C}B(0, \varepsilon)} \end{cases} \end{aligned} \quad (113)$$

$$= \begin{cases} -\frac{\mu_p - 1}{\mu_p + 2} e_3 & \text{in } B(0, \varepsilon) \\ -\frac{\mu_p - 1}{\mu_p + 2} \frac{\varepsilon^3}{|x|^3} \left(3(e_3 \cdot x) \frac{x}{|x|^2} - e_3 \right) & \text{in } \overline{\mathbb{C}B(0, \varepsilon)} \end{cases} \quad (114)$$

APPENDIX D. SOME RESULTS ON THE SPHERICAL SURFACE HARMONICS

Proposition 11. For $\ell \in \mathbb{N}$, the family of spherical harmonics $(Y_\ell^m)_{-\ell \leq m \leq \ell}$ satisfies:

$$\forall (\theta, \eta) \in [0, \pi] \times [0, 2\pi] \quad \sum_{m=-\ell}^{\ell} |Y_\ell^m(\theta, \eta)| \leq \frac{3\sqrt{3}}{\sqrt{4\pi}} \ell^{\frac{3}{2}}. \quad (115)$$

Proof. From the definition of Spherical Surface Harmonics, we have

$$\sum_{m=-\ell}^{\ell} |Y_\ell^m(\theta, \eta)| = \sqrt{\frac{2\ell+1}{4\pi}} \left(|P_\ell^0(\cos(\theta))| + 2 \sum_{m=1}^{\ell} \sqrt{\frac{(\ell-m)!}{(\ell+m)!}} |P_\ell^m(\cos(\theta))| \right).$$

The Legendre polynomial $P_\ell^0 = P_\ell$ is bounded by 1 and we have the following bounds for the Associated Legendre functions, see [17],

$$\forall m \in \{1, \dots, \ell\} \quad \sqrt{\frac{(\ell-m)!}{(\ell+m)!}} \max_{x \in [-1, 1]} |P_\ell^m(x)| \leq \frac{1}{\sqrt{2}}. \quad (116)$$

It follows that

$$\sum_{m=-\ell}^{\ell} |Y_\ell^m(\theta, \eta)| \leq \sqrt{\frac{2\ell+1}{4\pi}} (1 + \sqrt{2\ell}) \leq \frac{(2\ell+1)^{\frac{3}{2}}}{\sqrt{4\pi}} \leq \frac{3\sqrt{3}}{\sqrt{4\pi}} \ell^{\frac{3}{2}}.$$

□

Proposition 12. For $\ell \in \mathbb{N}$, the family of spherical harmonics $(Y_\ell^m)_{-\ell \leq m \leq \ell}$ satisfies:

$$\forall (\theta, \eta) \in [0, \pi] \times [0, 2\pi] \quad \sum_{m=-\ell}^{\ell} |\partial_\theta Y_\ell^m(\theta, \eta)| \leq \frac{\sqrt{3}(1+\pi)}{\sqrt{2\pi}} \ell^{\frac{5}{2}}. \quad (117)$$

Proof. Using the definition of the Spherical Harmonics, we get

$$\sum_{m=-\ell}^{\ell} |\partial_\theta Y_\ell^m(\theta, \eta)| \leq \sqrt{\frac{2\ell+1}{4\pi}} \left(|\partial_\theta(P_\ell^0(\cos(\theta)))| + 2 \sum_{m=1}^{\ell} \sqrt{\frac{(\ell-m)!}{(\ell+m)!}} |\partial_\theta(P_\ell^m(\cos(\theta)))| \right).$$

For $\ell \geq 1$, for $m \in \{1, \dots, \ell\}$ and for all $x \in]-1, 1[$, we have [1, 18]:

$$\begin{aligned} \partial_x P_\ell^0(x) &= \partial_x P_\ell(x) = -\frac{1}{\sqrt{1-x^2}} P_\ell^1(x) \\ \partial_x P_\ell^m(x) &= \frac{1}{2\sqrt{1-x^2}} \left((\ell+m)(\ell-m+1) P_\ell^{m-1}(x) - P_\ell^{m+1}(x) \right). \end{aligned}$$

It follows that, for $\ell \geq 1$, for $m \in \{1, \dots, \ell\}$ and for all $\theta \in [0, \pi]$, we have

$$\begin{aligned} \partial_\theta(P_\ell^0(\cos(\theta))) &= P_\ell^1(\cos(\theta)) \\ \partial_\theta(P_\ell^m(\cos(\theta))) &= \frac{1}{2} \left(P_\ell^{m+1}(\cos(\theta)) - (\ell+m)(\ell-m+1) P_\ell^{m-1}(\cos(\theta)) \right). \end{aligned}$$

Using relations (116), it follows that

$$\begin{aligned} \sum_{m=-\ell}^{\ell} |\partial_\theta Y_\ell^m(\theta, \eta)| &\leq \sqrt{\frac{2\ell+1}{8\pi}} \sum_{m=-\ell}^{\ell} \sqrt{(\ell+m)(\ell+1-m)} \\ &\leq \sqrt{\frac{2\ell+1}{8\pi}} \sum_{m=-\ell}^{\ell} \sqrt{(\ell+1)^2 - m^2}. \end{aligned}$$

By comparison to the quadrature rectangle rule, we have

$$\begin{aligned} \sum_{m=-\ell}^{\ell} \sqrt{(\ell+1)^2 - m^2} &= (\ell+1) + 2 \sum_{m=1}^{\ell} \sqrt{(\ell+1)^2 - m^2} \\ &\leq (\ell+1) + 2 \int_0^{\ell+1} \sqrt{(\ell+1)^2 - x^2} \, dx \\ &\leq (\ell+1) + \frac{\pi}{2} (\ell+1)^2. \end{aligned}$$

We conclude the proof using $2\ell+1 \leq 3\ell$ and $(\ell+1) + \frac{\pi}{2} (\ell+1)^2 \leq 2(1+\pi)\ell^2$. □

Proposition 13. For $\ell \in \mathbb{N}$, the family of spherical harmonics $(Y_\ell^m)_{-\ell \leq m \leq \ell}$ satisfies:

$$\forall (\theta, \eta) \in [0, \pi] \times [0, 2\pi] \quad \sum_{m=-\ell}^{\ell} \left| \frac{1}{\sin(\theta)} \partial_\eta Y_\ell^m(\theta, \eta) \right| \leq \frac{3\sqrt{3}}{2\sqrt{2\pi}} \ell^{\frac{5}{2}}. \quad (118)$$

Proof. Using the definition of the Spherical Harmonics, we express the sum in the LHS of (118) using the associated Legendre polynomials:

$$\sum_{m=-\ell}^{\ell} \left| \frac{1}{\sin(\theta)} \partial_{\eta} Y_{\ell}^m(\theta, \eta) \right| = \sqrt{\frac{2\ell+1}{4\pi}} \sum_{m=-\ell}^{\ell} \sqrt{\frac{(\ell-m)!}{(\ell+m)!}} \left| \frac{m}{\sin(\theta)} P_{\ell}^m(\cos(\theta)) \right|. \quad (119)$$

For $\ell \geq 1$, for $m \in \{1, \dots, \ell\}$ and for all $x \in]-1, 1[$, we have [1, 18]:

$$\frac{m}{2\sqrt{1-x^2}} P_{\ell}^m(x) = -P_{\ell-1}^{m+1}(x) - (\ell+m)(\ell+m-1) P_{\ell-1}^{m-1}(x).$$

It follows that, for $\ell \geq 1$, for $m \in \{1, \dots, \ell\}$ and for all $\theta \in [0, \pi]$, we have

$$\frac{m}{2\sin(\theta)} P_{\ell}^m(\cos(\theta)) = -P_{\ell-1}^{m+1}(\cos(\theta)) - (\ell+m)(\ell+m-1) P_{\ell-1}^{m-1}(\cos(\theta)).$$

Following the same steps as in the proof of Proposition 12, we conclude that

$$\begin{aligned} \sum_{m=-\ell}^{\ell} \left| \frac{1}{\sin(\theta)} \partial_{\eta} Y_{\ell}^m(\theta, \eta) \right| &\leq \frac{\sqrt{2\ell+1}}{2\sqrt{2\pi}} \sum_{m=-\ell}^{\ell} \sqrt{(\ell-m)(\ell-m-1)} \\ &\leq \frac{\sqrt{2\ell+1}}{2\sqrt{2\pi}} \sum_{m=-\ell}^{\ell} (\ell-m) \leq \frac{\ell(2\ell+1)^{\frac{3}{2}}}{2\sqrt{2\pi}} \leq \frac{3\sqrt{3}}{2\sqrt{2\pi}} \ell^{\frac{5}{2}}. \end{aligned}$$

□

APPENDIX E. L^p -NORM OF THE NORMAL DERIVATIVE OF GREEN'S KERNEL

Proposition 14. *For all $x \in \mathbb{R}^3$, we have*

$$\|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(S^2)} \leq A_3 \quad (120)$$

where $A_3 = \|\partial_n \mathcal{G}((1, 0, 0), \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(S^2)} \approx 0.3439$.

Proof. We proceed in two steps. First, we will compute the expression of $\|\partial_n \mathcal{G}(x^*, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(S^2)}$ for all $x^* \in S^2$. Then we will show that for all $x \in \mathbb{R}^3$, denoting by $x^* \in S^2$ the projection of x onto S^2 , we have

$$\forall y \in S^2 \setminus \{x^*\} \quad |\partial_n \mathcal{G}(x, y)| \leq |\partial_n \mathcal{G}(x^*, y)|. \quad (121)$$

For all $x^* \in S^2$ and $1 < p < 2$, let us consider the quantity

$$\mathcal{A} = \oint_{S^2} \left| \frac{n \cdot (x^* - y)}{4\pi |x^* - y|^3} \right|^p dy$$

where n denotes the outward unit normal to S^2 at $y \in S^2$. In order to compute \mathcal{A} , let us consider a frame centered on the point x^* and the following parametrization of the sphere S^2 :

$$(s, t) \in B(0, 1) \subset \mathbb{R}^2 \mapsto \begin{pmatrix} s \\ t \\ 1 \pm \sqrt{1 - s^2 - t^2} \end{pmatrix} \in S^2,$$

where the sign \pm is introduced to describe the two hemispheres. In this frame, the normal unit vector n to the sphere S^2 is given by

$$n = \begin{pmatrix} s \\ t \\ \pm \sqrt{1 - s^2 - t^2} \end{pmatrix}.$$

Since $|y|^2 = 2n \cdot y$, we have $\mathcal{A} = \mathcal{A}_+ + \mathcal{A}_-$ where

$$\begin{aligned}\mathcal{A}_\pm &= \frac{1}{(8\pi)^p} \iint_{s^2+t^2 < 1} \frac{1}{(2 \pm 2\sqrt{1-s^2-t^2})^{\frac{p}{2}}} \frac{\sqrt{1+s^2+t^2}}{\sqrt{1-s^2-t^2}} ds dt \\ &= \frac{1}{2^{\frac{7p}{2}-1}\pi^{p-1}} \int_0^1 \frac{1}{(1 \pm \sqrt{1-r^2})^{\frac{p}{2}}} \frac{\sqrt{1+r^2}}{\sqrt{1-r^2}} r dr.\end{aligned}$$

Using the change of variable $u = 1 \pm \sqrt{1-r^2}$, we deduce that

$$\mathcal{A} = \frac{1}{2^{\frac{7p}{2}-1}\pi^{p-1}} \int_0^2 \frac{\sqrt{1+2u-u^2}}{u^{\frac{p}{2}}} du.$$

For $p = \frac{4}{3}$, by evaluating \mathcal{A} by quadrature, we found $\mathcal{A} \approx 0.24093027$. Finally,

$$\|\partial_n \mathcal{G}(x^*, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(S^2)} = \mathcal{A}^{\frac{3}{4}} \leq 0.35. \quad (122)$$

In order to prove (120), we consider $x \in \mathbb{R}^3$ and we denote by x^* its projection onto S^2 . Considering the frame previously introduced and centered on x^* , the coordinate of x reads $(0, 0, -d)$ where $d = \text{dist}(x, S^2) \geq 0$. For any point $y \in S^2$, we deduce from the relation $|y|^2 = 2n \cdot y$ that

$$\left| \frac{n \cdot (x^* - y)}{|x^* - y|^3} \right| = \frac{1}{2|y|}.$$

Similarly, one can show that

$$\left| \frac{n \cdot (x - y)}{|x - y|^3} \right| = \frac{1}{2|x - y|} - \frac{d^2 + 2d}{2|x - y|^3}.$$

Since $d \geq 0$ and $|x - y| \geq |x^* - y|$ we directly deduce that

$$\left| \frac{n \cdot (x - y)}{|x - y|^3} \right| \leq \left| \frac{n \cdot (x^* - y)}{|x^* - y|^3} \right|$$

This last inequality implies that $\|\partial_n \mathcal{G}(x, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(S^2)} \leq \|\partial_n \mathcal{G}(x^*, \cdot)\|_{\mathbb{L}^{\frac{4}{3}}(S^2)}$. We conclude the proof of Proposition 14 using (122). \square
